Whatever the problem, it's a delivery issue, not a warranty issue (like the unit wasn't defective as supplied by ACOM).

Callum.

Ed,

You bought the amplifier used (yes, it was just a month old), and we facilitated the entire deal for you, including making all shipping arrangements for you and the seller at no cost to you.

When you discovered that you had a problem, we agreed to fix the amplifier for you as if it was new and under warranty - if you paid the shipping cost. And, the shipping cost was all you paid.

Since we did precisely what we agreed to do for you, and your amplifier was completely repaired under warranty two years ago, even though you were not the original purchaser, I'm not sure what you're unhappy with.

> not news to me.
>
Per my original post, what I found odd was that ACOM said the warranty terms were entirely determined by the dealer; i.e., there was no factory warranty per se. I also found it unusual that warranty details (the "fine print") were not published, either on paper or online. Maybe I was the only one who didn't know all this.
>
> I recall though that this wasn't a warranty issue at all, this was the

> the amp but charged you for postage both ways.
>
The reason the dreaded "Brown" service was chosen was that the dealer said he had a contract with that service which included no-nonsense insurance to protect me; otherwise, I would never have agreed to use them. However, when "Brown" damaged the shipment, the dealer did not cooperate in making an insurance claim; so I took the hit.
>
> The bottom line is that the dealer's delivery service apparently failed.

>
Per my original post, there was ALSO an ACOM defect: They omitted the internal stabilizer that might have protected the capacitor bank from "Brown's" brutality. (This according to the dealer.) That is why the warranty came into play.

Hi Bob,

Thank you for your input to this discussion. Before responding, I would like to point out that none of my posts identified the dealer involved in my ACOM purchase. And those posts were not intended to be a dealer-related complaint; the time for that is long past. I related my experience because it seemed relevant to the EBS discussions involving ACOM warranties.

But since you decided to discuss your role, in this forum, I will respond to specific points below...

Thanks, Ed

The seller wanted to ship FX; and I agreed that FX would be much less risky than the brutal Browns. However, even FX would have involved significant shipping risk. And I could not buy adequate insurance against that risk, because it simply isn't available to consumers. (FX will sell you a permit to file a claim, but not actual insurance.)

When that problem was brought to your attention, you said that as a big Brown shipper, you had big time insurance in your Brown contract. Then you kindly offered to arrange for shipping under your name, if reimbursed for the cost. That was much appreciated, and it SEEMED to resolve the shipping risk issue. So the whole deal went forward on that basis.

> When you discovered that you had a problem, we agreed to fix the amplifier

This is true as far as it goes, but is not the whole story.

1. I don't really accept describing the situation as "my" problem, given that I did nothing wrong, and that I was supposed to be protected by both a warranty and solid insurance. But let's not dwell on semantics.

2. You say here "AS IF it was... under warranty." The agreement we had was that the amp WAS under warranty, unambiguously. More semantics.

3. "If (I) paid the shipping cost" sweeps a problem under the rug: Web-published ACOM warranty descriptions say that RETURN shipping of warranty work to the customer is at ACOM/dealer expense. That representation was not honored, in this case. No explanation

given.

4. Probably ALL the extra shipping resulting from Brown mishandling should have been at Brown expense--had you elected to make or support an insurance claim; but you didn't. Again, no explanation given.

> Since we did precisely what we agreed to do for you, and your amplifier
> was completely repaired under warranty two years ago, even though you were
> not the original purchaser, I'm not sure what you're unhappy with.
>
Parts of this aren't true, and other parts aren't the whole story.

1. You didn't do "precisely what (you) agreed to do," because you failed to invoke the insurance coverage that you promised, and that was crucial to the deal.

2. My understanding of a warranty repair is that the repair will either be as good as new, or if that cannot be done, the unit will be replaced. Neither one happened in my case. The repair was crudely done, and to put it bluntly, it looks like one of my Junior High shop projects. And even if one overlooks the workmanship problems, the unit still wasn't "completely repaired." The spacer/stabilizer that you said the factory should have installed was still missing. But to be fair and balanced here, the repair WORKS just fine.

As to "what (I was) unhappy with," I think I explained that quite clearly in my original post; but here is an alternative version:

So far, no one has suggested ANYTHING that I did wrong during the course of this transaction. In fact, I correctly anticipated things OTHER players were going to do wrong (e.g., Brown shipping damage), and did everything possible to prevent or mitigate them. But in the end, I got stuck with two extra rounds of shipping expense, plus hours spent diagnosing, discussing, documenting, packing, and unpacking, plus about two months of lost use. And I now have a pricey amp that looks shabby on the inside, and is still missing a significant factory part (according to you).

Should I be a little unhappy about all that? It's a matter of opinion, I suppose. Maybe I'm just a grumpy, unreasonable guy. But getting back to the original post, it's not about me, and I'm not looking for sympathy. I was just trying to shine a little light on the mysterious world of ACOM warranties, in case that might help someone else avoid problems.

Hi Joel,

Silly me, I thought that ACOM warranty info WAS "information pertaining to their amplifiers"--especially in the context of a recent thread expressing concerns about EBS mod's "voiding warranties." Hmmm. My bad, I guess. 8~/

As I said in my most recent post, I'm not looking for group sympathy regarding my ill-fated ACOM purchase. But since someone decided to post comments on my situation that included factual errors and omissions, I felt the need to correct the record.

I can sympathize with your boredom, as I was hoping to watch the (rained out) World Series on the telly tonight. But if my posts are what's boring you, I respectfully suggest that you don't read them.

In any case, I agree with you that enough has been said on this in the forum. If anyone wants to continue the thread, I suggest doing so privately, via email. Fair enough?

Ed

4486. Acom 1000 repair: TRI indicator wildly moving from left to right and visa-versa

Yahoo group: acom-list (2010 — 2016)
Date: 2011-10-27 10:19:00 UTC
From: Kees - pa7two
Topic: 4486 Message: 4486

Hi Acom users,

About two months ago a new and
unexpected phenomenon started surfacing while using my Acom 1000.

The phenomenon was that the TRI
indicator wildly moved from left to right and back on the front-panel LCD while the amp was tuned and 'in use'. This happened when the tube/amp was a bit warmed-up, most noticeable when amp was used the first time after a long cool down.

The TRI was stable for several seconds,
then started wandering around, next stable again and yet the whole cycle repeated itself. When I let the AMP cool down for a prolonged period of time, the TRI was stable again for a short period of time. At first I inspected all coax / antennae, but the exact same TRI moving behavior occurred using a dummyload.

I contacted Acom in Bulgaria and got
prompt the same day a response with the first instructions to start with. These instructions mainly consisted of measuring the voltages on the main control board PCB (next to the LCD) to start with, this to determine which PCB was faulty. No irregular voltages could be found while conducting the various tests. Stan asked me to focus also on the C7 & C8 on the Wattmeter PCB, as this was a reported problem in one repaired Acom 1000. When at first no faulty components / unexpected voltages could be found, I replaced two the two capacitors on the Wattmeter PCB. This did at first gave an excellent result for about 6 hours of amp usage, but read on...the next day the TRI indicator walked again from left to right :-(

The next day I inspected again closely
the components on the Wattmeter PCB and again could not find anything unexpected. I decided to re-solder all components in charge of the Forward Detector Circuit (JP1:1) TRI voltages namely
D2, C7, C8, R9, C9, RP3, C10, R10, and R11. A questionable thing to do, since in general SMD devices are to be soldered just one time only...

Also
the resistor bed of RxA/RxB (8 resistors of 100 ohm each) were checked and when I touched one of the resistors, I noticed a movement of a 10th
of a millimeter of the R1B resistor body! (I used three magnifiers in cascade to observe this. If I had 'blinked 'my eyelid at the same

time, I would have missed this 'movement' for sure!)

When
I touched the solder-pad with a SMD solder-tool to suck the solderpad empty, the resistor fell off
the PCB, leaving a 10th
of millimetre of ceramic material to the other solder-pad. The
culprit was found. A cracked ceramic resistor body! Amp
in cold state the resistor value OK, when warm the resistor was
'open'. When measured with a multimeter, the push of the two
measuring multimeter pins against the ceramic body pushed the two
parts close enough to each other to measure the correct resistor
value (100 Ohm)...
Darn,
this was a real difficult one to trace. Visually nothing in error / unexpected could be observed when the resistor was factory soldered onto and in position on the PCB.

I
have to mention that Acom Bulgaria, namely Stan LZ1IU, and Acom's
'spare part shipping' department too, were (again) extremely helpful
finding the culprit in my Acom 1000 amp and sending out quickly the
spare parts. Many emails with helpful hints & tips and clear
instructions were provided every time I had to report that the
culprit was not yet found. It was the first time that Acom was
confronted with a broken resistor body on the Wattmeter PCB.

I
would like to write one last sentence here : A BIG 'thank you' to Acom
Bulgaria. A true superb after sales service! The amp is up &
running again, just in time for the SSB contest this weekend :-)

Vy 73, de Kees.

Ed,

The problem here is one of perception not of semantics.

A used amplifier - even one that is only a month old - is not under a warranty of any kind. That is a fact - not a semantic interpretation.

So there is no mystery - if you're not the original purchaser, there is no warranty.

We did you a favor - and we were under no obligation to do anything for you. In retrospect, I should have refused to get involved in this re-sale for the seller and to assist you with making the shipping arrangements.

You might not have bought the amplifier, and this discussion would not be happening.

So, our new policy is: never get involved in the resale of any of our equipment or offer to help with making shipping arrangements like we did in this case.

Your expectation of getting warranty treatment and support as if you had purchased the amplifier new from a dealer is where you went wrong.

If you wanted the luxury of having the privileges of an original owner, you should have paid the extra money to purchase a new amplifier yourself - it's really that simple.

Regarding what UPS would or would not cover - there is no way that UPS would pay for a capacitor flopping over sideways inside an amplifier.

If there's no apparent damage to the outside of the carton, they are unlikely to cover anything. This is just the fact of dealing with shipping insurance coverage.

I'm glad your amplifier is working perfectly and has been since we repaired it.

Subject: [acom-list] Re: ACOM Warranties and EBS

Hi Bob,

Thank you for your input to this discussion. Before responding, I would like to point out that none of my posts identified the dealer involved in my ACOM purchase. And those posts were not intended to be a dealer-related complaint; the time for that is long past. I related my experience because it seemed relevant to the EBS discussions involving ACOM warranties.

But since you decided to discuss your role, in this forum, I will respond to specific points below...

Thanks, Ed

The seller wanted to ship FX; and I agreed that FX would be much less risky than the brutal Browns. However, even FX would have involved significant shipping risk. And I could not buy adequate insurance against that risk, because it simply isn't available to consumers. (FX will sell you a permit to file a claim, but not actual insurance.)

When that problem was brought to your attention, you said that as a big Brown shipper, you had big time insurance in your Brown contract. Then you kindly offered to arrange for shipping under your name, if reimbursed for the cost. That was much appreciated, and it SEEMED to resolve the shipping risk issue. So the whole deal went forward on that basis.

> When you discovered that you had a problem, we agreed to fix the amplifier

This is true as far as it goes, but is not the whole story.

1. I don't really accept describing the situation as "my" problem, given that I did nothing wrong, and that I was supposed to be protected by both a warranty and solid insurance. But let's not dwell on semantics.

2. You say here "AS IF it was... under warranty." The agreement we had was that the amp WAS under warranty, unambiguously. More semantics.

3. "If (I) paid the shipping cost" sweeps a problem under the rug: Web-published ACOM warranty descriptions say that RETURN shipping of warranty work to the customer is at ACOM/dealer expense. That representation was not honored, in this case. No explanation given.

4. Probably ALL the extra shipping resulting from Brown mishandling should have been at Brown expense--had you elected to make or support an insurance claim; but you didn't. Again, no explanation given.

> Since we did precisely what we agreed to do for you, and your amplifier
> was completely repaired under warranty two years ago, even though you were
> not the original purchaser, I'm not sure what you're unhappy with.
>
Parts of this aren't true, and other parts aren't the whole story.

1. You didn't do "precisely what (you) agreed to do," because you failed to invoke the insurance coverage that you promised, and that was crucial to the deal.

2. My understanding of a warranty repair is that the repair will either be as good as new, or if that cannot be done, the unit will be replaced. Neither one happened in my case. The repair was crudely done, and to put it bluntly, it looks like one of my Junior High shop projects. And even if one overlooks the workmanship problems, the unit still wasn't "completely repaired." The spacer/stabilizer that you said the factory should have installed was still missing. But to be fair and balanced here, the repair WORKS just fine.

As to "what (I was) unhappy with," I think I explained that quite clearly in my original post; but here is an alternative version:

So far, no one has suggested ANYTHING that I did wrong during the course of this transaction. In fact, I correctly anticipated things OTHER players were going to do wrong (e.g., Brown shipping damage), and did everything possible to prevent or mitigate them. But in the end, I got stuck with two extra rounds of shipping expense, plus hours spent diagnosing, discussing, documenting, packing, and unpacking, plus about two months of lost use. And I now have a pricey amp that looks shabby on the inside, and is still missing a significant factory part (according to you).

Should I be a little unhappy about all that? It's a matter of opinion, I suppose. Maybe I'm just a grumpy, unreasonable guy. But getting back to the original post, it's not about me, and I'm not looking for sympathy. I was just trying to shine a little light on the mysterious world of ACOM warranties, in case that might help someone else avoid problems.

I disagree on this. In general it does matter to have this kinda feedback information before you buy a product from a manufacturer. What one can expect of the warranty and most importantly, what not. That is generically applicable for buying an Acom amp, but also for instance when buying something completely different like a new TV set for in the living-room or kitchen cooker.

Fortunately it is very different in my country when it comes to warranty & Acom, see my last posted message about my latest Acom 1000 repair. The factory in Bulgaria gave excellent feedback & instructions and service too in sending spareparts in multiple occasions when one of my the two Acom amps was in error in the past.

This is how we in general experience Acom's after sales service here in Europe: >> UFB!

Hi,
I understand nothing, I purchase Acom 2000A, on november 2000, I have had some problems before finished warranty and the Acom Team Europe (Bulgaria) gave to my an excellent service in warranty time and also when finish the warranty, all solved without any problem in 2011 is working 100% as the first day eleven years after purchase.
I congratulate everytime the Acom Service Team for her user attention.

4491. Acom 1000 repair: TRI indicator wildly moving from left to right and visa-versa (Added info abt TX mode used during testing)

Yahoo group: acom-list (2010 — 2016)
Date: 2011-10-27 13:47:50 UTC

Hi Acom users, (Added info abt TX mode used during testing)

About two months ago a new and unexpected phenomenon started surfacing while using my Acom 1000.

The phenomenon was that in CW keydown mode the TRI indicator wildly moved from left to right and back on the front-panel LCD while the amp was tuned and 'in use'. This happened when the tube/amp was a bit warmed-up, most noticeable when amp was used the first time after a long cool down.

The TRI was stable for several seconds, then started wandering around, next stable again and yet the whole cycle repeated itself. When I let the AMP cool down for a prolonged period of time, the TRI was stable again for a short period of time. At first I inspected all coax / antennae, but the exact same TRI

moving behavior occurred using a dummyload.

I contacted Acom in Bulgaria and got prompt the same day a response with the first instructions to start with. These instructions mainly consisted of measuring the voltages on the main control board PCB (next to the LCD) to start with, this to determine which PCB was faulty. No irregular voltages could be found while conducting the various tests. Stan asked me to focus also on the C7 & C8 on the Wattmeter PCB, as this was a reported problem in one repaired Acom 1000. When at first no faulty components / unexpected voltages could be found, I replaced two the two capacitors on the Wattmeter PCB. This did at first gave an excellent result for about 6 hours of amp usage, but read on...the next day the TRI indicator walked again from left to right :-(

The next day I inspected again closely the components on the Wattmeter PCB and again could not find anything unexpected. I decided to re-solder all components in charge of the Forward Detector Circuit (JP1:1) TRI voltages namely D2, C7, C8, R9, C9, RP3, C10, R10, and R11. A questionable thing to

do, since in general SMD devices are to be soldered just one time only...

Also the resistor bed of RxA/RxB (8 resistors of 100 ohm each) were checked and when I touched one of the resistors, I noticed a movement

of a 10th of a millimeter of the R1B resistor body! (I used three magnifiers in cascade to observe this. If I had 'blinked 'my eyelid at the same

time, I would have missed this 'movement' for sure!)

When I touched the solder-pad with a SMD solder-tool to suck the solderpad empty, the resistor fell off the PCB, leaving a 10th of millimetre of ceramic material to the other solder-pad. The culprit was found. A cracked ceramic resistor body! Amp in cold state the resistor value OK, when warm the resistor was 'open'. When measured with a multimeter, the

push of the two measuring multimeter pins against the ceramic body pushed the two

parts close enough to each other to measure the correct resistor value (100 Ohm)... Darn, this was a real difficult one to trace. Visually nothing in error / unexpected could be observed when the resistor was factory soldered onto and in position on the PCB.

I have to mention that Acom Bulgaria, namely Stan LZ1IU, and Acom's 'spare part shipping' department too, were (again) extremely helpful

finding the culprit in my Acom 1000 amp and sending out quickly the spare parts. Many emails with helpful hints & tips and clear instructions were provided every time I had to report that the culprit was not yet found. It was the first time that Acom was confronted with a broken resistor body on the Wattmeter PCB.

I would like to write one last sentence here : A BIG 'thank you' to Acom Bulgaria. A true superb after sales service! The amp is up & running again, just in time for the SSB contest this weekend :-)

Subject: [acom-list] Acom 1000 repair: TRI indicator wildly moving from left to right and visa-versa

Hi Acom users,

About two months ago a new and

unexpected phenomenon started surfacing while using my Acom 1000.

The phenomenon was that the TRI

indicator wildly moved from left to right and back on the front-panel

LCD while the amp was tuned and 'in use'. This happened when the

tube/amp was a bit warmed-up, most noticeable when amp was used the

first time after a long cool down.

The TRI was stable for several seconds,

then started wandering around, next stable again and yet the whole

cycle repeated itself. When I let the AMP cool down for a prolonged

period of time, the TRI was stable again for a short period of time.
At first I inspected all coax / antennae, but the exact same TRI
moving behavior occurred using a dummyload.
I contacted Acom in Bulgaria and got
prompt the same day a response with the first instructions to start
with. These instructions mainly consisted of measuring the voltages
on the main control board PCB (next to the LCD) to start with, this
to determine which PCB was faulty. No irregular voltages could be
found while conducting the various tests. Stan asked me to focus also
on the C7 & C8 on the Wattmeter PCB, as this was a reported
problem in one repaired Acom 1000. When at first no faulty components
/ unexpected voltages could be found, I replaced two the two
capacitors on the Wattmeter PCB. This did at first gave an excellent
result for about 6 hours of amp usage, but read on...the next day the
TRI indicator walked again from left to right :-(
The next day I inspected again closely
the components on the Wattmeter PCB and again could not find anything
unexpected. I decided to re-solder all components in charge of the
Forward Detector Circuit (JP1:1) TRI voltages namely
D2, C7, C8, R9, C9, RP3, C10, R10, and R11. A questionable thing to
do, since in general SMD devices are to be soldered just one time
only...
Also
the resistor bed of RxA/RxB (8 resistors of 100 ohm each) were
checked and when I touched one of the resistors, I noticed a movement
of a 10th
of a millimeter of the R1B resistor body! (I used three magnifiers in
cascade to observe this. If I had 'blinked 'my eyelid at the same
time, I would have missed this 'movement' for sure!)

When

I touched the solder-pad with a SMD solder-tool to suck the solderpad empty, the resistor fell off

the PCB, leaving a 10th

of millimetre of ceramic material to the other solder-pad. The

culprit was found. A cracked ceramic resistor body! Amp

in cold state the resistor value OK, when warm the resistor was

'open'. When measured with a multimeter, the push of the two

measuring multimeter pins against the ceramic body pushed the two

parts close enough to each other to measure the correct resistor

value (100 Ohm)...

Darn,

this was a real difficult one to trace. Visually nothing in error / unexpected could

be observed when the resistor was factory soldered onto and in position on the PCB.

I

have to mention that Acom Bulgaria, namely Stan LZ1IU, and Acom's

'spare part shipping' department too, were (again) extremely helpful

finding the culprit in my Acom 1000 amp and sending out quickly the

spare parts. Many emails with helpful hints & tips and clear

instructions were provided every time I had to report that the

culprit was not yet found. It was the first time that Acom was

confronted with a broken resistor body on the Wattmeter PCB.

I

would like to write one last sentence here : A BIG 'thank you' to Acom

Bulgaria. A true superb after sales service! The amp is up &

running again, just in time for the SSB contest this weekend :-)

I firmly believe that this discussion is important if only to allow informed decisions as to repair options when home repair gets past your abilities.

My experience
My 2000A was purchased used and out of warranty so there is no doubt that I had to pay all expenses.
This has been a while ago and my memory will cause a few details to be fuzzy.
My amp exhibited a bias error with no warning and was operation shortly before the error at 1450 watts with no strain and everything working very well.
After several conversations with Jay and Bob and running many tests I decided that the amp needed more expertise than I have.
I arranged to have the amp hand delivered to them(a 6 hour drive).

Now some background
The original owner had talked to the factory before purchase and was assured that EVERYTHING in this amp could be repaired in the US no matter what happened and this was one of the considerations to his purchase and my later purchase from him.

They worked on the amp for several weeks with many calls to the factory including changing out the tubes for known good tubes.
Since the amp was hand delivered they had my transformer to test with the amp.
It was finally decided that the amp would need to be returned to Bulgaria for repair at my expense estimated to be around $600.00.

As a comment along the way Jay and Bob put many hours into this amp and I don't think they charged me anything for their time and I am very happy with their efforts.

At the factory the amp was supposedly repaired and after another 3 months or so finally returned. I drove to Dallas and hand picked up the amp. The bill was slightly less than $2000.00 including shipping.

I got home and set it up and had a high voltage error.

At this point I ran basic tests including the interlock switches and decided that after spending that much money I did not want to make any changes until Acom had it working.

I drove back to Dallas and the amp hit the bench within minutes of me walking in the door and they worked on it until I was forced to leave the next day with no success.
They later found that one of the interlock switches would check good to an ohm meter but would not work under load.
Several more hours from Bob and Jay that they did not get paid for.

I then had a friend pick up the amp and hand carry it back to me and it has worked fine since then.

My problems with this are with the factory repair.
1) I do not believe it needed a new set of tubes.

2) They did not return my old tubes
3) they did not give any explanation of the problems found and I was not able to get any explanation after the fact even though I asked many times.
4) on inspection the amp was still dirty on the inside and was obviously not inspected and cleaned
5) the amp was obviously not tested as a final stage before shipping it back to me.
6) I feel that the price was very excessive for what I can learn was done

Sorry for the long post but feel it is necessary
I love the amp and if I had known what I do now would have purchased a new one or an Alpha it would have cost less.

Roger

Given that I now run my own business here in the UK, I certainly resent Paul's comment.

Furthermore, I recently needed help from MFJ, and they couldn't even be bothered to reply.

Given that I now run my own business here in the UK, I certainly resent
Paul's comment.

Furthermore, I recently needed help from MFJ, and they couldn't even be
bothered to reply.

4497. Acom 1000 - Temperature Reading

Yahoo group: acom-list (2010 — 2016)
Date: 2011-10-28 13:21:59 UTC
From: gm4znc@aol.com
Topic: 4497 Message: 4497

Hi guys

As chance would have it, just before a contest, my Acom 1000 Exhaust Air Temperature reading states: Exh. Air -16C 0F constantly during standby & use. The amplifier appears to working fine during general use (CW & SSB only) including the normal operational temperature rises and the tube appears to be cooled by the internal fan.

Any guidance would be appreciated.

73

Hi guys

As a follow up to my last request, I have received an excellent response from Ron at Vine Antennas (UK) explaining the problem & its solution.

It would appear "this fault has often been traced to the expiry of C1 and C2 on the temperature sensor board...." & "...are best replaced with regular wire-ended components...", so if anyone else has a similar problem !

Thanks for the bandwidth & many thanks to Ron (Vine Antenns).

Hi Mike

I bought the amplifier in September 2008 (second owner) & it was approximately 1 year old then, so 4 years +/- some months.

It did not nor has had much use during that time but from Rons description, it appears to be a known 'problem' which looks easy enough to repair (hopefully).

Enjoy your forthcoming summer.

Cheers, Beers & 73

Forum members: I apologize for using more bandwidth on this.

My original point was to give warranty info to the Forum. But I made the mistake of using my own case as an example, and now posts about my case have drowned out my intended topic.

I will make no more Forum posts on this, even if other posts misrepresent the facts of my case. I'm available by email if further discussion is needed.

Bob,

I will point out (again) that I did not identify you as the dealer involved in my situation; you chose to identify yourself.

Also, please note that I'm trying to put this mess in the past, and I don't want to hold a grudge. I wish you, Array Solutions, and ACOM success.

That said, several of your latest comments require a response. Please see below...

I have no problem with you making a no-warranty policy. ACOM told me directly that US dealers determine warranty terms entirely. (That was one of the points I was trying to make in my original post.)

However, I must point out some relevant facts:

1. You personally told me before the transaction that you would accept a full warranty transfer to me. (And no, I didn't get it in writing.)

2. For perspective, ACOM seems to consider it OK to transfer warranties; and your counterpart on the East Coast has told me directly that he accepts such transfers.

3. It was *you* who introduced the warranty angle in the first place, by pointing out ACOM's omission of the cap stabilizer. (I think it would have been better to pursue a straight UPS damage claim. UPS doesn't know about the stabilizer, and they shouldn't have dropped the box!)

> We did you a favor - and we were under no obligation to do anything for you.

I agree completely that you owed me *nothing* going in, as I've said before. But I can't agree that you did me any favors by making promises that you couldn't or wouldn't keep.

> In retrospect, I should have refused to get involved in this re-sale for the
> seller and to assist you with making the shipping arrangements.
>
I don't blame you at all for feeling that way. I also regret my involvement. (I'm the one who took the losses, after all.)

> You might not have bought the amplifier, and this discussion would not be

That is your prerogative. Alternatively, you could assist your customers as before, but avoid making promises that you can't keep. It's your business, and your decision. I respect that 100%.

> Your expectation of getting warranty treatment and support as if you had
> purchased the amplifier new from a dealer is where you went wrong.
>
> If you wanted the luxury of having the privileges of an original owner, you

Excuse me Bob, but the reason I had full warranty expectations is because YOU told me that I would have full warranty coverage. Should I apologize for believing that?

> Regarding what UPS would or would not cover - there is no way that UPS would
> pay for a capacitor flopping over sideways inside an amplifier.
>
The whole bank of cap's were folded flat. They are quite light. The leads are quite stiff. A UPS-style impact would be required to produce the necessary g-forces. We had photos of the cap's, before and after the impact.

> If there's no apparent damage to the outside of the carton, they are
> unlikely to cover anything. This is just the fact of dealing with shipping
> insurance coverage.
>
The shipping carton was only moderately damaged--apparently because it landed flat on its end, and not on a corner. The shipping document did not have a check box for "moderate" damage, so the condition was recorded as "crushed." (I have an email on that.) There should have been no problem with the documentation.

> I'm glad your amplifier is working perfectly and has been since we repaired
> it.

Yes the amp has worked fine, as I pointed out in my first post. Thank you again for your functional (not cosmetic) repair.

Except for about $200 lost on extra shipping, about $200 more lost on resale value because of internal scars (my estimate), about two months of lost use, many hours lost corresponding about it, and the disappointment of broken promises, I'm a happy camper.

Alpha honors second and third and fourth owners as long as it is during the warranty period and transferred. Flex does the same. Yaesu did for me on a quadra I purchased as the second owner, no questions asked. There are companies out there that take good care of their customers.... by the way, Yaesu also upgraded ALL ftdx9000d's worldwide regardless of whether you were the first or 10th owner. They did so free of charge with no need to transfer warranties. They did it for everyone, knowing that it would go a long way toward customer loyalty. It cost me almost $1000 to upgrade my Icom 7800. My reaction? Sell the 7800 and buy a second ftdx9000d. In general, most high end equipment is comparable and the companies aren't selling equipment. They are selling loyalty, customer support and a smile, handshake and a "we will take care of you if you put your trust in us" (Steve Jobs Apple).

I purchased a Steppir Big IR Mark 2. It was 90 days old when I purchased it three years ago. The copper strip failed at the 10 month time line. They knew I was the second owner. They repaired it no charge under warranty. Three years later (last month) the steppir motor failed. They sent me a new one no charge. The good will they generated will pay them back manifold. I push Steppir antennas to everyone I know and tell them about how they treated me as a second owner of their product! Top quality guys.

And the stated below is EXACTLY what a customer expects when buying his products. Being the 1st, 2nd or whatever buyer, we are treated as per stated below and is common sense in EU. We had these kinda customer 'treatments' in the past, fortunately by law when it comes to warranty things have changed dramatically positive.

I have no problem with you making a no-warranty policy. ACOM told me directly that US dealers determine warranty terms entirely. (That was one of the points I was trying to make in my original post.)

However, I must point out some relevant facts:

1. You personally told me before the transaction that you would accept a full warranty transfer to me. (And no, I didn't get it in writing.)

2. For perspective, ACOM seems to consider it OK to transfer warranties; and your counterpart on the East Coast has told me directly that he accepts such transfers.

3. It was *you* who introduced the warranty angle in the first place, by pointing out ACOM's omission of the cap stabilizer. (I think it would have been better to pursue a straight UPS damage claim. UPS doesn't know about the stabilizer, and they shouldn't have dropped the box!)

> We did you a favor - and we were under no obligation to do anything for you.

I agree completely that you owed me *nothing* going in, as I've said before. But I can't agree that you did me any favors by making promises that you couldn't or wouldn't keep.

> In retrospect, I should have refused to get involved in this re-sale for the

> seller and to assist you with making the shipping arrangements.

>

I don't blame you at all for feeling that way. I also regret my involvement. (I'm the one who took the losses, after all.)

> You might not have bought the amplifier, and this discussion would not be

> happening.

>

That is true.

> So, our new policy is: never get involved in the resale of any of our

> equipment or offer to help with making shipping arrangements like we did in

> this case.

>

That is your prerogative. Alternatively, you could assist your customers as before, but avoid making promises that you can't keep. It's your business, and your decision. I respect that 100%.

> Your expectation of getting warranty treatment and support as if you had

> purchased the amplifier new from a dealer is where you went wrong.

>

> If you wanted the luxury of having the privileges of an original owner, you

> should have paid the extra money to purchase a new amplifier yourself - it's

> really that simple.

>

Excuse me Bob, but the reason I had full warranty expectations is because YOU told me that I would have full warranty coverage. Should I apologize for believing that?

> Regarding what UPS would or would not cover - there is no way that UPS would

> pay for a capacitor flopping over sideways inside an amplifier.

>

The whole bank of cap's were folded flat. They are quite light. The leads are quite stiff. A UPS-style impact would be required to produce the necessary g-forces. We had photos of the cap's, before and after the impact.

> If there's no apparent damage to the outside of the carton, they are

> unlikely to cover anything. This is just the fact of dealing with shipping

> insurance coverage.

>

The shipping carton was only moderately damaged--apparently because it landed flat on its end, and not on a corner. The shipping document did not have a check box for "moderate" damage, so the condition was recorded as "crushed." (I have an email on that.) There should have been no problem with the documentation.

> I'm glad your amplifier is working perfectly and has been since we repaired

> it.

Yes the amp has worked fine, as I pointed out in my first post. Thank you again for your functional (not cosmetic) repair.

Except for about $200 lost on extra shipping, about $200 more lost on resale value because of internal scars (my estimate), about two months of lost use, many hours lost corresponding about it, and the disappointment of broken promises, I'm a happy camper.

Ed and list members, I apologize for extending this discussion any further.

As we all know, there are two sides to every story, and this one is no exception.

I'm not going to comment any further.

73,

Bob W5OV

Hello Bob,

The temperature regime indeed is a non-issue. After the EBS-mod I did
not notice any rise in the Acom 2000S's temperature, even not during 24
hours contesting.
My modulation however was significantly improved after the mod.

Hi George,

Long time! Hope you are well.

I just want to let you know about an experience I had with my Acom antenna switch. For some time I experienced erratic behavior when changing switch positions. To make a long story short, it turned out that some of the little blue bypass caps sprinkled all over the PCB inside the switch were failing. Replacing those bad caps made everything work perfectly again.

Topic: 4443 Message: 4509

HI MARK,

I too have been watching the EBS comments and wonder if you have a list of what production lot numbers are affected? I purchased my used Acom in 2001 from Krassy and aside from one tube going bad, no other issues. Also, is Barry's comment below conclusive to determine if I have the problem?

Is it possible to "predict" whether there are EBS artifacts on your tx audio
by monitoring the BIAS voltage in the MEASURE menu as you transmit? For
example, if you see the BIAS level often transitioning from -87V to -66V
while speaking, then it probably does (does not?) mean your tx signals has
audible artifacts?

Barry N1EU

Thanks and 73's

Steve

K1IIG

Gentlemen

It's very simple, the EBS-Problem depends on the production lot of the amps, I have several of them out of various production lots, running in different installations on a 24/7 base, one of them had that modulation problem, others give a crystal clear modulation and don't need any mods. Did the mod on one of my installations, modulation is excellent now, temperature level is raising a little bit faster, but no problem with the aux fan, never had heat faults.

The acoms are great amps, a real masterpiece of rf-engineering (eg. have a look for the outstanding emc-design-details), except the crappy firmware which makes it difficult to write any reliable control application for the amp.

An: acom-list@yahoogroups.com
Betreff: [acom-list] Re: EBS electronic bias user update - Acom comments

I apologize for stirring up a hornet's nest!

I am leaving all the replies below this as reference etc.

NOW....everyone take a breath and relax!

EBS electronic bias system has been a design characteristic in
tube amplifiers for many many years! From Ameritron to Alpha
etc.

The design is to reduce tube on time between words etc...
The rational is to have the tubes last longer, and reduce
dissipated heat....

Now ALL amplifiers using EBS demonstrate some sort of anomaly.
Most hams who simply contest or DX with the driver by QSO:
"yer 5/9 QRZ" or "yer 5/9 -257 good luck" may not observe the EBS
anomaly.

Those of you with hearing challenges may not hear the EBS anomaly.
Those of you listening very narrow 350-2400hz may not hear the
anomaly.

Many folks using tube amplifiers with an EBS circuit are unaware of
the anomaly unless told since this happens after the radio and you
will not hear it in your radio monitor.

Those of you with dirty signals...slight to considerable RFI on
your signal, AC him, room noises etc. may not be aware of the
EBS anomaly.

Many Ham's have no clue what to listen for, so your buddies in the daily rag-chew will tell you "ya sound fine like you always do"

Now.....the reality of the EBS design may cause that crunch anomaly
based upon a variety of operator styles. How you speak, how you
pronounce words, pauses between words, how you address the microphone, how much of your breathing/breath noise you
introduce etc.

EBS crunch is REAL and can be distracting!!!!!!!

The solution is very simple....if you could care less.....
IGNORE IT!

I take pride in how I represent myself on air...I speak well,
I DO NOT use "and-um, you-know, bad English, bad grammar"
and all the other poor speech styles.

To me having a pure non polluting SSB audio signal is important and I'm willing to sacrifice a few hours of tube life or additional heat for a quiet clean amplified signal.

Ameritron and Alpha have information [if asked] regarding adjusting their EBS system. For example I believe the Alpha 8410 EBS can be
adjusted via your computer interface.

The ACOM 2000A has no EBS adjustment and that's perfectly fine and not worth attacking ACOM or their design team! They also decided not
to make it an issue in their design and that's fine too!

WE have a number of options here:

1. leave the amplifier EBS system alone
2. disable the EBS system
3. install a switch to turn the EBS on/off as desired
4. calculate the time constant and adjust the resistor or
capacitor value to speed up or slow down the EBS switching time
5. attack those that do modify the EBS circuit

So for all you "design engineer experts bantering on this topic" please stop bashing ACOM!!!

Their amplifiers are beautiful machines! Stop bashing those
of us that prefer NOT to use EBS! It's our choice.

If you are so head strong regarding this EBS design or topic go send a resume to ACOM, ALPHA, AMERITON, etc and use your talent to help them redesign their amplifier EBS system....

The rest of you...go get a cup a coffee and enjoy the amplifier
and get on the air instead of hanging around all the reflectors ha!

4510. ACOM 1010 failure out of the box

Yahoo group: acom-list (2010 — 2016)

Topic: 4510 Message: 4510

Hello!

I purchased in December last year a new ACOM 1010 from Array Solutions. The amp trips into fault after a brief period of use preceded by the G2 LED flashing. Sometimes, I don't even have to transmit in order for the G2 LED to blink. Closing the PTT can cause it sometimes. Here is the history:

After nearly six months, I finally got the amp on the air during WPX CW in May. I was using a generator, which frankly wasn't all that well regulated. 250 VAC without a load but checked 230-240 @ 55-60 Hz under load. It had a nominal 240 VAC output. (I had the amp wire for 240.) Over time, The G2 light would come on. I checked tuning, which was fine. The drive was never any more than 60 watts. I even dropped the drive to 30 watts, and it did the same. G2 would eventually flash for several seconds even in between transmit cycles, as if it was temperature related. I selected maintenance mode. G1 shows no LED reflections (no current?), G2 and Ip were within normal limits. Sometimes, not always, if I switched to standby mode, after the G2 light flashed (but had stopped), all the LEDs would light up and flash. Following the instructions, I naturally switched off the amp. Powered again, and it seemed to be fine, but after some use, the same thing would occur.

I tried to use it again for Field Day in June with the same results. My assumption was, and seconded by BobN at Array Solutions, was that the unstable generator power could be associated. I did not use the amp again until CQWW SSB this past weekend, I finally got good commercial power @ 240 VAC and 60 Hz, and fired up the ACOM 1010 for the first time since Field Day. No more generators. The amp has lost its mind. Wondering if there is something I can troubleshoot further, or if I should just ship it back to Array Solutions for repair.

Sequence as follows:

Tuned up on 15m with 20 watts input just fine, and we settled at 45 watts drive. Within minutes of a few test calls, the G2 LED began flashing again, and it lingered quite a while after I quit transmitting. Checked tuning, no problem. A few more calls, and it tripped into fault mode. Turned it off and let it sit for about 20 minutes before trying again. Tuned right up and worked flawlessly in S&P mode (mostly, with a lot of idle time) on 80-10m for the next 18-20 hours. Finally, the G2 LED began flashing again during a solid run on 15m, and the amp tripped into fault.

This happens on all bands and antennas. Antennas are all fed with RG-213 and VSWR < 2:1 (< 1.5:1 typical) on all bands.

I notice at times the indicated power increases rather dramatically at times with a fixed input. For instance, from a cold start, on 20m I tune

it up OK and with 30W drive it puts out ~400-450W. After a 5 minutes of warm up and a few CQs the LEDs indicate 600W peak, and around this time the G2 LED will begin flashing.

I put it into diagnostic mode when it did this:

G1 illuminated - no green LEDs deflected.
G2 illuminated - 10 LEDs deflect when idle. When I transmit, another green LED comes on, then dims and goes out after I cease to TX.
IP illuminated - 9 green LEDs illuminate on transmit.

The G2 flashes even when I'm not transmitting. The "hang time" for G2 flash will get longer and longer. If I press the OPER button while it's flashing, all the FWD and REF LEDs flash, the G2 LED stays solid, and F LED is off.

The G2 LED will flash now after 5-10 minutes warm-up without a transmitter even being connected.

Finally, I notice the isolation between A1 and A2 inputs is rather poor. When the unused (and unterminated) port is selected, I can still hear signals on the transceiver, although they are attenuated quite a bit (S9+10 dB reduces to S4-S5). Is this normal?
I will ship it back to A-S on Friday if I don't get some answers by then.

From: Markus Schleutermann
Topic: 4443 Message: 4511

Hi Steve

The ACOM with the BIAS-problem was bought in 2009, on older versions I never had the problem. To evaluate the problem just listen to your audio, when it sounds scratchy after speech breaks when regaining rf level for a short time then you have the problem. I think the measurments are to slow to determine the problem.

73 de Mark, HB9AZT

Von: acom-list@yahoogroups.com [mailto:acom-list@yahoogroups.com] Im Auftrag von Steve Tripp (K1IIG)
Gesendet: Freitag, 21. Oktober 2011 12:36
An: acom-list@yahoogroups.com
Betreff: Re: AW: [acom-list] Re: EBS electronic bias user update - Acom comments

HI MARK,

I too have been watching the EBS comments and wonder if you have a list of what production lot numbers are affected? I purchased my used Acom in 2001 from Krassy and aside from one tube going bad, no other issues. Also, is Barry's comment below conclusive to determine if I have the problem?

Is it possible to "predict" whether there are EBS artifacts on your tx audio
by monitoring the BIAS voltage in the MEASURE menu as you transmit? For
example, if you see the BIAS level often transitioning from -87V to -66V
while speaking, then it probably does (does not?) mean your tx signals has
audible artifacts?

Barry N1EU

Thanks and 73's

Steve

K1IIG

Gentlemen

It's very simple, the EBS-Problem depends on the production lot of the amps, I have several of them out of various production lots, running in different installations on a 24/7 base, one of them had that modulation problem, others give a crystal clear modulation and don't need any mods. Did the mod on one of my installations, modulation is excellent now, temperature level is raising a little bit faster, but no problem with the aux fan, never had heat faults.

The acoms are great amps, a real masterpiece of rf-engineering (eg. have a look for the outstanding emc-design-details), except the crappy firmware which makes it difficult to

write any reliable control application for the amp.

Betreff: [acom-list] Re: EBS electronic bias user update - Acom comments

I apologize for stirring up a hornet's nest!

I am leaving all the replies below this as reference etc.

NOW....everyone take a breath and relax!

EBS electronic bias system has been a design characteristic in
tube amplifiers for many many years! From Ameritron to Alpha
etc.

The design is to reduce tube on time between words etc...
The rational is to have the tubes last longer, and reduce
dissipated heat....

Now ALL amplifiers using EBS demonstrate some sort of anomaly.
Most hams who simply contest or DX with the driver by QSO:
"yer 5/9 QRZ" or "yer 5/9 -257 good luck" may not observe the EBS
anomaly.

Those of you with hearing challenges may not hear the EBS anomaly.
Those of you listening very narrow 350-2400hz may not hear the
anomaly.

Many folks using tube amplifiers with an EBS circuit are unaware of
the anomaly unless told since this happens after the radio and you
will not hear it in your radio monitor.

Those of you with dirty signals...slight to considerable RFI on
your signal, AC him, room noises etc. may not be aware of the
EBS anomaly.

Many Ham's have no clue what to listen for, so your buddies in the daily rag-chew will tell you "ya sound fine like you always do"

Now.....the reality of the EBS design may cause that crunch anomaly
based upon a variety of operator styles. How you speak, how you
pronounce words, pauses between words, how you address the microphone, how much of your breathing/breath noise you
introduce etc.

EBS crunch is REAL and can be distracting!!!!!!

The solution is very simple....if you could care less.....
IGNORE IT!

I take pride in how I represent myself on air...I speak well,
I DO NOT use "and-um, you-know, bad English, bad grammar"
and all the other poor speech styles.

To me having a pure non polluting SSB audio signal is important and I'm willing to
sacrifice a few hours of tube life or additional heat for a quiet clean amplified signal.

Ameritron and Alpha have information [if asked] regarding adjusting their EBS system. For
example I believe the Alpha 8410 EBS can be
adjusted via your computer interface.

The ACOM 2000A has no EBS adjustment and that's perfectly fine and not worth attacking ACOM
or their design team! They also decided not
to make it an issue in their design and that's fine too!

WE have a number of options here:

1. leave the amplifier EBS system alone
2. disable the EBS system
3. install a switch to turn the EBS on/off as desired
4. calculate the time constant and adjust the resistor or
capacitor value to speed up or slow down the EBS switching time
5. attack those that do modify the EBS circuit

So for all you "design engineer experts bantering on this topic" please stop bashing
ACOM!!!

Their amplifiers are beautiful machines! Stop bashing those
of us that prefer NOT to use EBS! It's our choice.

If you are so head strong regarding this EBS design or topic go send a resume to ACOM,
ALPHA, AMERITON, etc and use your talent to help them redesign their amplifier EBS
system....

The rest of you...go get a cup a coffee and enjoy the amplifier
and get on the air instead of hanging around all the reflectors ha!

My Acom 2000A is from seven years ago and I had the EBS problem too.

The best way to determine if you have the EBS-crunch is let somebody who
lives very near to you listen to your SSB-signal. In other words: when
your signal is strong.
Speak with as many intervals between your words as possible; then they
will notice the EBS-crunch easy.

> Hi Steve
>
> The ACOM with the BIAS-problem was bought in 2009, on older versions I never had the problem. To evaluate the problem just listen to your audio, when it sounds scratchy after speech breaks when regaining rf level for a short time then you have the problem. I think the measurments are to slow to determine the problem.

Hi All,

I have got a power-up problem on my ACOM1000. When turning on the switch on the backside of the PA, the upper line of the LCD display is showing only balks(as if the output is 1200W) and the red LED on the front is not flashing. The amplifier can not be turned on at all, I dont even get an error code on the display.
The day before it happend and the ampifier was finally not powering up anymore, I have realized the same already for a moment. But after a short time (I guess 10 seconds) the balks disappeared and the PA was ok. Looks as if something was dying slowly.

The ACOM-service advised me to send the PA to my dealer, since it seems to be a difficult to find +5V problem on the mains or control PCB. I can understand the advice, but being in Dar es Salaam thats not really an option... The CQWW CW is coming soon...hi.

Has anybody had a similar problem before and remembers what happend?

Hello Mike,

I used to have an Acom 1000, but never experienced that problem. I currently have both a 2000A and a 1010 but, again, have not had that problem or any other problem for that matter.

If possible, you could send your amp to Array Solutions in Dallas for repair. I understand that they do a good job with the Acom amps. I understand your difficulty in doing that from 5H3, however.

Back in the 60's, I lived in Asmara, Ethiopia, now Eritrea, and was very active from ET3USA for 3 years. As they say, "them were the good old days", hi.

Tnx for the Qsos in WW SSB. We also worked 5Z4EE. Are you two stations related in some way? Just curious because you are both signing EE suffixes.

Hope to work you in WW CW.

Hi Mike,

Best thing I guess is to ask Acom Bulgaria for advise. Maybe a quick (but expensive) swap of the main controller PCB can do wonders...

Thinking about it, if you know another HAM with an Acom 1000 close by, maybe you can swap his front-panel on your amp and see if the error is still there. That way you know of the main controller/LCD display PCB is in error. I did the same trick with the resistor fix on the Wattmeter PCB problem I described recently here on the reflector. Made it a lot easier to trace which PCB is in error.

Assuming you took a look inside the amp, re-seated the white coloured connectors on the PCBs etc?

Being unaware of your skills: Remember ==> Work safe! ALWAYS wait at least 30 minutes after shut down of the amp before opening it! Shortcut with an HV insulated screwdriver the HV lead to the tube short to ground first if you are needed to come even close to the HV section of the amp. Use eye protection when doing so. Be extremely careful while measuring on / at the HV side of the amp. Of course, all of this at your own risk!

Vy 73, de Kees.

Larry I do not understand your note about A1 and A2 inputs, and selecting the unused port. I don't get the part about "selecting the unused port".

I have an Acom 1010, and it has only 1 input. It does, however, have two outputs, A1 and A2, for two antenna selections.

Finally, I notice the isolation between A1 and A2 inputs is rather poor. When the unused (and unterminated) port is selected, I can still hear signals on the transceiver, although they are attenuated quite a bit (S9+10 dB reduces to S4-S5). Is this normal?

Mike,

Had a similar problem with the LCD display going nuts.
It turned out to be two bad electrolytic caps according to the factory.
Look on the top PCB for electrolytics which appear swollen or are leaking.

Yes, antenna selectors, George. All the ports (TX, A1, A2) are bi-directional, of course. My normal config is FT-950 -> TX, Antenna -> A1, No connection -> A2. When I select A2, I can still hear signals.

I want to echo Brian's comment - bad electrolytic caps are common problem in the older 1000's. The early amps used some electrolytic caps not rated for the harsh environment inside a power amp (i.e. temperature rating). Very often they'll fail and sure signs are either leaking the electrolyte (whitish/brownish residue around the cap) or swelling of the aluminum can like they are about to explode or both. A failed cap could sink the power bus voltage of the CPU board (+5V). Take a careful look at the MAIN board (above the power transormer). The CPU board is shielded behind the front panel. Most caps have a stress relief point on top of the can - it looks like an "X". The can should crack open at this point to relief internal pressure instead of bursting - look for electrolyte residue there.

Andrey,

First, many thank to you for your blog data concerning VNA 'OSL' terminations! Wow, what a world of difference it makes with return loss repeatability when using Amphenol, rather than "Brand X" Asian imports. Anyone interested in knowing how do construct precision 50-ohm terminations for VNA testing purposes would do well to see Andrey's work.

That out of the way, I agree with your cap analysis. Observation of the stress relief point is a good practice at regular maintenance intervals. However, I am surprised this issue should present itself at all. Of all the PS electrolytics I've recently changed in amps, it was done as a preventative measure, rather than by failure. Electrolytic caps produced in the last 10-15 years seem to be especially reliable. So, if anyone has accurate information concerning the root-cause failure of the early ACOM 1000 PS caps, please pass it along.

Paul, W9AC

Larry.

Interesting. I will have to try selecting A2 with an antenna only
connected to A1.

BTW, why would you even select A2 if it does not have an antenna connected?

Hi Paul,
thanks for the nice words.

As for the "root cause", I didnt want to elaborate (so nobody over at ACOM gets offended - you know, pride and such) but since you are interested, I'll give you my take. The amps are build in the ACOM factory in Sofia, Bulgaria and they used to source most of the parts from "Eastern Bloc" countries with a lot of parts comming from Bulgaria and Russia. I guess the main reason was the low cost of such components.
The capacitor factory in Bulgaria - then-called "ZZK", (located in the town of Kyustendil) is a communist-era factory - not particularly known for high quality caps. In general, the quality standards for consumer-grade electronic parts back-then-and-there (late 80's-early 90s) were not the greatest. Probably same holds true for other non-mil-grade parts comming from such factories. In my ACOM 1000 I had a lot of caps on the MAIN board manufactured in the Kyustendil factory. You can recognize them by the stylized logo with the schematics symbol for capacitor and the letter "K".
I would only asume that nowadays they manufacture better quality caps.

> I want to echo Brian's comment - bad electrolytic caps are common problem in the older 1000's. The early amps used some electrolytic caps not rated for the harsh environment inside a power amp (i.e. temperature rating). Very often they'll fail and sure signs are either leaking the electrolyte (whitish/brownish residue around the cap) or swelling of the aluminum can like they are about to explode or both. A failed cap could sink the power bus voltage of the CPU board (+5V). Take a careful look at the MAIN board (above the power transormer). The CPU board is shielded behind the front panel. Most caps have a stress relief point on top of the can - it looks like an "X". The can should crack open at this point to relief internal pressure instead of bursting - look for electrolyte residue there.

Hi,

Unless Acom have used something more exotic than a simple change over relay then 30dB isolation between antenna ports is about all you can expect. Greater than that requires rather more effort and at least three relays. It pays to remember this when having multiple antennas connected due to the possibility of injecting noise from the off line antenna into the receive path.

Thank you, Mike. I assumed the isolation between A1/A2 might be better, but I never looked at the relay or the schematic, for that matter. Under normal operating conditions I would have only one antenna connected to the amp, but I do occasionally configure with two for convenience of switching.

Mike,

Right on. Guys forget this when using multiple radios into a common amp or antenna. At 100 watts one can pump more RF into the unused radio than some can handle. Extra relays to provide more isolation and also ground the antenna terminal of the used rig may be required.

Isolation generally decreases with increasing frequency. So with 10M openings common, it may be time to assess if one has enough rig-to-rig isolation. If one operates 6M the problems get worse.

One way to do this is with an oscilloscope attached to a 50 ohm resistor on the unused radio relay port. Time to consider action if you get more than a volt or two.

My understanding is there are some "high isolation" antenna switches available. Even those are less than 50 db.

BTW high relay switches with big contacts can have less isolation that lower power relays. My guess is the larger contacts have more capacitive coupling than smaller contacts. It depends on the contact spacing as well.

The Acom 1010 has no coax high vacuum high speed relays mounted as in the Acom 1000. The Acom 1010 uses cheaper type switch relays. I am not surprised to read these results actually.

..just do a google search on BAD CAPS sometime. :-) Bad electrolytic caps almost put some computer manufacturers out of business. 85C temp rated caps are often used where 105C are needed. It would not surprise me at all that older amps will have bad caps. Remember around 2000 when one Asian company "stole" the formula for making electrolytic caps, made a gazillion then found out the formula was "bad..." resulting in all those gazillion caps failing?

Hello,

thanks to all of you for your input. The good thing first: The PA is working!

The one advice from Kees was the crucial hint. I have had disconnected and reconnected all the connectors on the mains PCB before, but not on the controller PCB behind the front panel. After doing it this morning the problem was already solved.
Honestly, before the WWSSB I did not spend to much time searching for the fault. I was busy with bringing my brocken beam back up in the air and had already planned before to go on LP 10m. Thanks George & Kees for the QSOs.

The amplifier is almost new, bought in december 2010. Therefore the electrolytic capacitors were newer ones. Anyway, I did check them - nothing was to be seen.
For your information: I have had another fault in february, a PN27 error. Together with Igor/UA3DJY we did find out, that the 3MOhm resistor of the HV indicator was having a too low value. So the ADC was always seeing an overvoltage...

George, I was also surprised, when I did hear the 5Z4EE the first time, but there is no relation. Actually, I would no cw-operator wish to have this EE suffix....terrible when going for S&P in a contest.

Thanks again to all! Now CQWW CW can come... Kees, I am owing you a 5band-QSO...Hi.

thanks to all of you for your input. The good thing first: The PA is

working!

The one advice from Kees was the crucial hint. I have had disconnected and

reconnected all the connectors on the mains PCB before, but not on the

controller PCB behind the front panel. After doing it this morning the

problem was already solved.

Honestly, before the WWSSB I did not spend to much time searching for the

fault. I was busy with bringing my brocken beam back up in the air and had

already planned before to go on LP 10m. Thanks George & Kees for the QSOs.

The amplifier is almost new, bought in december 2010. Therefore the

electrolytic capacitors were newer ones. Anyway, I did check them - nothing

was to be seen.

For your information: I have had another fault in february, a PN27 error.

Together with Igor/UA3DJY we did find out, that the 3MOhm resistor of the HV

indicator was having a too low value. So the ADC was always seeing an

overvoltage...

George, I was also surprised, when I did hear the 5Z4EE the first time, but there is no relation. Actually, I would no cw-operator wish to have this EE suffix....terrible when going for S&P in a contest.

Thanks again to all! Now CQWW CW can come... Kees, I am owing you a 5band-QSO...Hi.

4537. 2000a PC can't power on/off nor stb/opr switch

Yahoo group: acom-list (2010 — 2016)
Date: 2011-11-12 16:52:12 UTC
From: dl2cc@yahoo.de
Topic: 4537 Message: 4537

Hi all,

I know it has been asked before but what is wrong if I can read the meter and status of the 2000a just fine from acomtools and trxmanager but I just can't switch the amp on/off nor back to OPR if it is in STB mode.

I use the adapter from dxsupply.com and the supplied cable with a FTDI USB serial port on Windows 7.

Any help is appreciated before I go nuts!

Thanks 73

Welcome to the fraternity, Jeff!

Early models had some bad connectors and caps that caused trouble, but newer units are rock solid. I got one of the first units sold in the US and had these failures. All is good now. It's a killer amp!

An incredible amp !!

Nothing beats it and I will never sell my 2K!

I worked cqww a few weeks back and doubled my all time score, of course conditions were great but how much time
do we really waste load and plating those other amp ??

It was so smooth to move around with all that power, be heard the first call and just push out a very strong and solid signal.

I love my 2K !

Hi Olivier,
My 2000A is 2 years old. Runnig time is 2.946 hours, revision code: 5.0. Never use more than 1 kw or 400 watts on RTTY. Tubes and rest of settings are whitin its specifications. I do some contest ocasionally, never do qsk. Replaced the vacuum relay recently (not a difficult task). I switch on the amp everyday for a few hours althought I could use it or not. The amp remains in 30 Celsius while in stand by and could easily reach its 60 or 65 C while in use. I have the extra fan installed (never heard it running) and have 3 extra fans around the amp in a cabinet (2 blowing and 1 extracting the air off the shelf). Hope this help. 73

Olivier,

If you are referring to the tubes (lamps), I have had my 2000A since late 1998 and it still has the original tubes and they work as well as a new amplifier.

I don't know how many hours are on the tubes, but it has been used in every major contest since I got it - all modes including RTTY plus it has been to Antigua 3 times as baggage on American Airlines. I think it is a very rugged and reliable amplifier overall.

Sure, there are some who have had trouble from time to time, but generally speaking I think most have experience like I have, where it just does its job.

Over the history of my amp, it had some filament supply connectors that had to be replaced under warranty shortly after I purchased it and the vacuum relay had to be replaced about 4 years ago. Aside from that, it has been trouble free.

73,

Bob W5OV

Topic: 4545 Message: 4545

Hi Oliver.. I have approx 6000 hours on one and 3500 hours on another. The 6000 hour amp has had one tube replaced. Tom (sk) of Tom's tubes, used to say they were good for 3500 hours average, but I always thought that number was too low. The 2000A has an excellent cooling system and that's part of the key to long life. It has excellent protection circuits too.

hello

Thanks everybody for your answers.
I have one tube in stock , will buy another one even if i need them in 10 years...hehe
This amp is fantastic !
After 1010, this 2000 is nice too

Hi Olivier,
One tube is a good idea for an Acom 1000. But assuming that your Acom 200 has 2 tubes inside, that tubes must be MATCHED PAIR...
it means that they must be within similar specifications (as close one to each other as possible). Vinecom in UK is selling them as MATCHED PAIR and fully tested, just in case you need them. 73

This may be Kinda Dumb, But will effect the Placing on my Amp on Tuesday.
HOW warm/Hot does the Top of the Amp Get? I know the 2 Fans are on top, But I'm thinking of sitting it on the bench next to the radio (Think I Uploaded a Picture of the Shack in Photo section (N8NOE). If I Sit it on the Bench the TV/7700 Monitor would sit on top of it...

Jeff,

I'm not really sure what you are asking. The paragraph you have written is pretty jumbled up and I'm having difficulty trying to determine what you are really wanting to know.

If you are referring to an Acom 2000A, there are no fans on top of it. There is one fan on the rear.

You mention placing a TV/7700 on top of the amp. I don't know what a TV/7700 is, but I recommend that you do NOT place anything on top of the amp.

You ask how warm/HOT does the top of the amp get. I have never taken a temperature reading, but mine gets hot enough that I wouldn't want to place my hand over the tube vents.

In my case, my amp sits behind my operating desk. It sits on a wooden platform that I built with four 2" wheels. The amp sits about 4" above the floor. With the platform on wheels, I can scoot the amp around easily when I need to move it. The control head sits up on my operating desk.

What do you have in terms of 220 vac service for the amp?

Actually it has a blower inside the Amp
near the Tubes. If it has the optional fan it is on the rear right side. All have a filter on the right rear but may not have the optional fan.

4556. RE: [acom-list] Re: Tube Life

Yahoo group: acom-list (2010 — 2016)
Date: 2011-11-14 09:32:44 UTC
From: Kees - pa7two
Topic: 4545 Message: 4556

I agree on this statement. As long as the two tubes do not differ much temperature wise (easy to check in an Acom 2000a) that is as close as one needs to go when it comes to the topic 'tube matching' for an Acom2000a. Sure, I can see the emails coming about the discussion what the maximum difference should be... Well, here we go: Would a 10-20 degrees Celsius difference between the tubes be 'matched' enough for an Acom 2000a?

A match of <5% is nice to have, easy to observe because both tubes show then the same temperature curves, sure. Personally, I would like a 'matched' tube pair too for my amps. But the question is : Is it needed in the Acom 2000a? Out of experience I can ventilate the following: Very very often if the tubes are from the exact same production batch, the match is more than close enough. (Read: ** Close **). Exceptions to the rule are apply of course.

About average tube life: Around 3500-5000 Hours (with again exceptions to this rule, less than 800 Hours and over 7200 Hours in example) is my experience. When it comes to the lower hours tubes, in general in all cases the amps were fully loaded with dust, filter never cleaned and often used (at or near full output) with RTTY mode. A proper loading and cooling the GU74B tubes seems to be essential for an happy tube and it's life span!

Hi

Thanks Kees and all others for the comment.
Here, i've installed the extra fan, temps of the tubes are around 70 deg in long QSO. 40 in shorts.
Use most often around 500w so nothing suffering
Bought this amp just for autotune and because it's acom, not for the power.
Had a 1010 before and was so happy that i was obliged to have an automatic amp but only acom !

George;
Thanks, I'll be getting the 2000A in Tomorrow. the Icom IC-7700 is the Radio. I had a 20A/220V service in for the PW-1 I had in here, and the amp Stayed cool from an External fan that blew across the side of it and behind. I was told the 2000A had the 2 Fans/Blowers on the Top left Rear for the Tubes, and the one in rear was an option. But yes my Question was on the TOP of the 2000A the Cover itself.
Seems my Picture needs OK to be posted but you could see I want to set the AMP next to the Icom, but I use a TV sitting there as a Monitor for the Radio also...

The top cover doesn't get hot Jeff. Just be sure to not block the openings over the tubes.

Hi Jeff,

You definitely DO NOT want to obstruct the air flow from the tube chimneys, so don't EVER put anything atop those vents. Likewise with the rear of the unit, where it sucks in the cool air.

That said, there's still a fair amount of real estate atop the unit where it seems to be OK to put things. I don't know if there's a "x number of inches away from the chimneys" rule, but if you're other gadgets are 4 or more inches from the chimneys, you should be OK.

The exhaust air gets pretty hot. The cabinet gets warm, but nothing to be concerned about. If your hot air from the tubes is free to blow high in the room, you should be fine.

>
> I agree on this statement. As long as the two tubes do not differ much temperature wise (easy to check in an Acom 2000a) that is as close as one needs to go when it comes to the topic 'tube matching' for an Acom2000a. Sure, I can see the emails coming about the discussion what the maximum difference should be... Well, here we go: Would a 10-20 degrees Celsius difference between the tubes be 'matched' enough for an Acom 2000a?

Stan from Acom Bulgaria characterized the tube match as follows:

>12 degrees C temperature difference and you need to find a replacement or work at reduced power
10-12 degrees C difference is the maximum that is okay
4-8 degrees C difference is a proper match
<=6 degrees C difference is an excellent match

FYI, this information is all contained in the document "Tube Tips" in the files section under troubleshooting tips. Please people - upload any diagnostic help info you receive from Bulgaria and add to this folder.

Hi Jeff,

Yes, a photo would help. When you get your amp set up, pse send me a photo.

Just to clarify, the fan on the rear of the amp is standard. Since I do not have the optional fan, I don't know where it would be located. In my case, I run my 2000A hard in cw and phone contests, and never provide any cooling other than the stock fan that is in the amp. I do not run RTTY, so that may require additional cooling, but I don't really know.

Your 220 vac service for your PW-1 should be plenty adequate.

Yes, you can put your hand on the cover and, no, it does not get warmer
than that. The hot spot is over the tubes.

The optional fan is located right rear. If you have one mounted on the right rear back panel you indeed have the optional fan.
Standard is a blower located inside the Amp near the tubes.

Now comes the real question: What would be the real percentage of the mismatch when it comes to let say 12 degrees Celsius difference between two tubes?

Lets put a value here = 25% mismatch? (extreme)

Anyone?

>

> I agree on this statement. As long as the two tubes do not differ much temperature wise (easy to check in an Acom 2000a) that is as close as one needs to go when it comes to the topic 'tube matching' for an Acom2000a. Sure, I can see the emails coming about the discussion what the maximum difference should be... Well, here we go: Would a 10-20 degrees Celsius difference between the tubes be 'matched' enough for an Acom 2000a?

Stan from Acom Bulgaria characterized the tube match as follows:

>12 degrees C temperature difference and you need to find a replacement or work at reduced power

10-12 degrees C difference is the maximum that is okay

4-8 degrees C difference is a proper match

<=6 degrees C difference is an excellent match

FYI, this information is all contained in the document "Tube Tips" in

the files section under troubleshooting tips. Please people - upload

any diagnostic help info you receive from Bulgaria and add to this

folder.

Ill answer Kees, if we can clarify the question. By "12 C difference between the two tubes" do you mean 12 C in exhaust temp, or 12 C in tube temp? If the difference in exit air is 12 C, the difference in tube envelop temp is greater than 12 C. At what operating conditions shall we do the analysis?

What is the definition of mismatch? Difference between the percent of load each tube is carrying?

The answer lies in the question!

73 Hal N4GG

Now comes the real question: What would be the real percentage of the mismatch when it comes to let say 12 degrees Celsius difference between two tubes?

Lets put a value here = 25% mismatch? (extreme)

Anyone?

Hi Hal,

I assume 12 degrees Celsius difference a-la the method the Acom 2000a amps measures the temperature, and that is most likely the exhaust temperature.

I am curious what the answer will be. Would like to know for (all in degrees Celsius):

Hi Hal,

Forgot to mention in my previous reply, but let's stick to the temperature difference between tubes and take it from there. This because Acom refers to this way of measuring the "match".

Definition of mismatch, let's take the method that comes the closed to the 25% I gave as an example ha ha. Now without joking (...) yeah, the difference between the percent of load between each tube is a good start-point unless you have other thoughts on the matter?

From: Bob Naumann
Topic: 4570 Message: 4571

Jeff,

The amp will trip out at 200w as that exceeds the allowable input level.

If the amp is turned on and you want to run less than 1500 w output, turn down the drive from your radio and run less power output from the amplifier.

There is no reason to run 200w out of your radio when you can do so effortlessly from your amplifier.

If you don't want to use the amplifier, turn it completely off.

Don't mess with the aux/man tuning for a while. Just use the amplifier at its default tuning settings until you get used to it.

As long as your SWR is fairly good, you should have no trouble with using the default tuning of the amplifier. Watch the reflected power and reduce the drive from your radio to keep the reflected power down.

If your SWR is not good, you should put the time and effort into resolving the poor SWR as the results will pay greater dividends over time.

Actually, if I recall correctly . . . the amp will complain when in Standby mode and trying to run 200w from the radio through to the antenna. As Bob says, I believe it won't complain if the power is completely turned off (at the RCU - you don't have to turn off the main power switch on the amp chassis). Someone please confirm.

QSL, this I Guess would have been a Little Better Way to ask the Question..
I'm Taking today off, and expecting the PowerStation meter in the Brown Truck today. Need to get that in-line and Read/Re-Read the manual more.
My First 3 QSO's on the AMP were remarkable!.
First was a Friend in Austin that knows my Voice and can compare it over time, Was told it could not have been better. Second was a guy Listening in the Delta Region of LA. Chimed in and watching his scope commented on the Clean signal. 3rd, was with T2T on 15 RTTY.
IT all is playing very nice here so far..
THANKS ALL for tips and help. Menus, Settings, This button, that button.. Does get a bit confusing at times..

Because antennas have different loading characteristics, you can teach the amp which antenna you are on by switching "virtual" antennas. On a contest station for instance, you may have three of four different antennas for the same band. Changing from a low dipole to say a high dipole on 80m means that you should tune the amp again, but not the Acom. You teach the amp0lifier which antenna to tune for and re-select the antenna with in operation. I forget the sequence, I am away from the 2000 right now.

I believe the antenna switch will allow you to do this automatically; change antennas *and* change the amplifier tuning.

(I have probably used too many words for this description, I apologise but I currently have "man-flu" illness, hence the confusion!).

I never had luck in the early days of the 2000A being able to select a
second antenna (via some signal external to the 2000). Wanted the
equivalent of an A/B switch for a single band. Switching in the antenna
via the manual switch was easy, getting the ACOM to follow by switching
to another antenna and use new tunings was not possible.
(Not talking about using the high priced ACOM antenna switch)

Perhaps this is possible today with a program, it wasn't (within
WINDOWS) back then.

4582. Acom Director setup help?

Yahoo group: acom-list (2010 — 2016)
Date: 2011-11-19 00:20:35 UTC
From: Bruce
Topic: 4582 Message: 4582

Hi,
I am trying to control my 2000a with Acom Director and I am struggling. I am using a boot camped Mac Pro with Windows 7 32 bit. I am also using an RT-Systems usb serial converter to connect the Acom RPON module to the computer. The software will turn the amp on and it will read the information shown in the remote but nothing else is working. No error messages but no control, I cannot shut the amp off, I cannot switch from standby to operate etc. Anyone have any thoughts on where I should begin? Perhaps the settings that I need for the port would be a good place to start?
Thanks,
Bruce AB1KC

Bruce;
New Guy Here but a Fellow Mac User.. If your able to see and Get information from the Software (I just looked it up, Nice Looking and may try it) your USB port settings are or Should be Fine. I'd see NO reason that would be an issue. Myself Use VMWare, and Parallels at work, and can control a Lot that way, and once you get the port to see, you should be fine.. NOT a lot of help, But would be nice is some would understand there are a lot of MAC users out here also..

I am also using an RT-Systems usb serial converter to connect the Acom RPON module to the computer. The software will turn the amp on and it will read the information shown in the remote but nothing else is working. No error messages but no control, I cannot shut the amp off, I cannot switch from standby to operate etc. Anyone have any thoughts on where I should begin? Perhaps the settings that I need for the port would be a good place to start?

4584. Palstar HF-Auto & ACOM 2000A?....

Yahoo group: acom-list (2010 — 2016)

From: ** N8NOE **
Topic: 4584 Message: 4584

Anyone Using the Palstar HF-Auto and the 2000A?..
Any Thoughts?

I'm looking into the Idea of an Auto Tuner as to give more Bandwidth and help the Poor Little Dipole (Doublet) out here.
Looks like the Newer Version can handle 2500w, and has done away with the Need for CI-V Cables?

Jeff-N8NOE

Hello Jeff,

The Palstar HF Auto Tuner is for coax. Coax is 50 Ohm; you cannot change that. I don't find full specs on the site of Palstar, but I assume the HF Auto Tuner handles impedances between 15 and 250 Ohm. Such tuners are nice to use when you have tuned antennas with little bandwidth.

When you want much more bandwidth with your dipole the only right way to go is open feederline and a symmetrical tuner (all balanced).

E.g. the PA0LL LL-Tuner (IMHO the best symmetrical - fully balanced - tuner in the world) easily handles impedances between several Ohms and several kiloOhms (!) and easily handles a few kiloWatt output power. For test purposes I tried full power from my Acom 2000A and the double-L LL-Tuner handles this with any problem. With only one dipole (or better: loop) you are able to tune between 1.5 and 30 (perhaps 60) MHz...

Nice weekend and 73!

Hello Elan,

Very nice to meet you again!

The antennetuner of DC9DZ, with the famous Kellermann balun, looks good
and very impressive. The only objection I have is that this tuner is not
balanced. Since I use fully balanced double-L tuners for the deltaloop
antenna I have noticed a lot of benefits. Not only in easy tuning and
high efficiency, but also in the almost complete absence of RFI/TVI,
even with the fabulous QRO from the Acom 2000A. The more balance you
have in your antennasystem, the better it is for everything.

Nice weekend and 73!

4588. RE: [acom-list] Acom Director setup help?

Yahoo group: acom-list (2010 — 2016)
Date: 2011-11-19 10:38:43 UTC
From: James Thresher
Topic: 4582 Message: 4588

Hi Bruce,

ACOM Director should work fine with windows running on the Mac, provided that the serial adaptor is operating correctly, it is likely that the problem lies with the cable. Normally if you are connecting directly from the computer to the ACOM2000 you will need a three wire null modem cable, however it is possible that the ACOM RPON module provides the necessary crossover of the RX & TX wires, so a regular RS232 cable would likely be needed in this case.

The COM port settings are fixed in the software as they are the same for all ACOM2000's.

I have had a report of a very similar issue to yours and it turned out to be a jumper setting in the RPON Module.

Let me know how you get on.

Subject: [acom-list] Acom Director setup help?

Hi,
I am trying to control my 2000a with Acom Director and I am struggling. I am using a boot camped Mac Pro with Windows 7 32 bit. I am also using an RT-Systems usb serial converter to connect the Acom RPON module to the computer. The software will turn the amp on and it will read the information shown in the remote but nothing else is working. No error messages but no control, I cannot shut the amp off, I cannot switch from standby to operate etc. Anyone have any thoughts on where I should begin? Perhaps the settings that I need for the port would be a good place to start?
Thanks,
Bruce AB1KC

Hi Jeff & any other Mac users,

ACOM Director is written using something called the Microsoft .NET Framework, There is a group of people that have produced a ported version of this that runs on the Mac called Mono. If I get the time over the winter, I will try and produce a native Mac version of the software, which would save having to run VMWare, Bootcamp or parallels.

Bruce;
New Guy Here but a Fellow Mac User.. If your able to see and Get information from the Software (I just looked it up, Nice Looking and may try it) your USB port settings are or Should be Fine. I'd see NO reason that would be an issue. Myself Use VMWare, and Parallels at work, and can control a Lot that way, and once you get the port to see, you should be fine.. NOT a lot of help, But would be nice is some would understand there are a lot of MAC users out here also..

Thanks James,
The Acom RPON came with a cable and I just plugged it in, I'll check to verify that it is a straight serial cable first and then I'll try another serial adapter.

The old Palstar Auto Tuner has connection for both coax and open feeder line. Either output can be selected and programmed. I don't know what the new versions has, but a call to Palstar should solve that problem.

I use the old Palstar Auto Tuner with my Acom, but I rarely turn it on since I have tuned antennas and only need the tuner near the band edges. Both work great together, but I do use the computer control to select the band and frequency.

I found the problem!
It seems that in designing the RPON module Acom makes the assumption that you will be using the A2000S automatic antenna switch and designs the circuit with that use in mind. In reading the schematic I found a note that says to wire a jumper between pins #2 and #3 if you are not using the A2000S. These are green and white wires in my module. I soldered the jumper at the board and voila It all works perfectly now! Perhaps a heads up to perspective RPON users would be nice as there is no mention of the need for a jumper in the literature until you look at the schematic.

4594. Ten-Tec Omni 6+ w 2000A

Yahoo group: acom-list (2010 — 2016)
Date: 2011-11-19 19:47:55 UTC
From: Barry N1EU
Topic: 4594 Message: 4594

I modified an Omni 6+ to incorporate the recommended circuit change in TenTec.doc in the group files section and connected it to my 2000A via TX EN / TX OUT.

It seems to work fine in CW. But in PTT or VOX SSB, I am getting "Detected RF Power at Wrong Time".

Has anybody successfully interfaced an Omni 6+ using TX EN/OUT in SSB?

(in the meantime, I'll use the relay output of the Omni 6+)

Thanks & 73,
Barry N1EU

Well, I am still getting "Detected RF Power at Wrong Time" in SSB using the Omni 6+ relay output instead of the TX EN/OUT loop.

Is ANYBODY successfully using an Omni 6+ in SSB with the 2000A?

Thanks & 73,
Barry N1EU

Barry,

There may be subtle timing differences between the Omni Six and Paragon. The mod shown in the Yahoo file appears to have been conducted on a Paragon.

Did you confirm that the amp is not hot-switching in CW even though the RCU shows no timing error? In the Omni Six, there may be timing differences between SSB and CW mode. I do know that when I purchased my 2000A in 1999, I confirmed that my Omni Six T/R mod from the early '90s resulted in super-fast and perfect timing in both CW and SSB modes. The mod requires use of the "T" line sample and is available at several points in the rig.

Unless the system can be timed with a scope, I would not use TX OUT/TX EN on anything but a TT amp.

Barry,

Just for grins, try this on the Omni Six. It's an easy change that's reversible:

1) Locate the Ext. amp relay's driving transistor and base resistor;

2) Lift the end of the resistor furthest away from the transistor and simply tie it to the "T" voltage bus;

3) Cut the PCB trace that goes from the transistor's collector to one side of the amp reply. After cutting, bring the collector directly out to the Ext. Amp RCA jack;

4) In the Omni Six menu, disable the Ext. amp relay;

5) Key the 2000A using only the standard key in line. In other words, one RCA cable from the Omni's Ext. Amp Key Out to the ACOM's key in jack.

See what happens with timing.

I heard back from Stan at Acom Bulgaria on this issue. There were factory updates/mods issued from 2000-2004 to make the 2000A compatible with the Ten-Tec Paragon and Omni 6.

I have added the additional info to the group files section.

It was too easy previously to find the TenTec.doc file in the group files section and be misled into thinking that would solve the problem.

Topic: 4510 Message: 4603

In following up, I wanted to say how pleased I am with the response to the problem I had with my ACOM 1010. Factory guidance suggested it was either a leaky cap on the main power supply board, or a bad tube. After basic checks on the caps, I sent the unit back to Array Solutions, and Jay confirmed a bad tube. The warranty repair was prompt. I had the amp back late Friday just in time for Sweepstakes SSB. It worked like a charm with no issues whatsoever. Many thanks to ACOM and A/S for the good support.

No idea why that is happening. When my 2000A is in standby, it truly is in standby and bypasses any input from the transceiver. However, since my tx is a K3 which does not run more than 100w, I have never tried the 2000A with anything more than 100w in standby.

There is a power limit on what the 2000 can pass in STBY.
The input (trcvr) relay is not QRO capable, only the output
(antenna) relay which safely handles 1500W +.
This is the same with other amps and not a design flaw.
I think you should stay at 100w or less. The warning comes on
at 150w as you say, so I would suggest 100w as a good choice.

That is correct. I have an Icom IC775dsp and an IC-7700
any power level beyond 150W with the amp in standby the RCU
will give you an alarm notification.

I recall reading this specification in some information documents early on with the 2000A.
I put mine into service around 09-2001

You may want to search the older files on the reflector.

This is not an unusual infant failure of the amplifier.
No rhyme or reason why it happens.

Usually it's a failed bias transistor or a bad/leaky capacitor
within the bias circuit.
yes new components do fail and that's why there is a warranty during
the amplifier's early years

My 2000A is about 11 years old and in the first year I experienced
the exact same anomaly

do report back with results.

They split ways with the designer of the AT-Auto and this one is an all new design. I use the AT-Auto (older model) with the Acom 2000. I do not use the CIV or RS232 interface. It senses RF frequency and tunes to the nearest memory freq and then tweaks it if needed. The older AT-Auto had a Balun output to drive a balanced line. Later they modified it to allow switching between two coax antennas. I would assume that by enlarging the coil and increasing the plate spacing on the caps they could up the power rating. The only band I have had problems on is 160M. I changed the line length and got it working on that band. PalStar is very good to work with.

Check out http://kesslerengineeringllc.com/ for an updated version of the one I have.

Kjeld,

As I recall, Acom has software for controlling the 2000SW. I tried it at one time, but decided not to use it. I simply control my 2000SW from the buttons on the 2000S.

Check with Acom for the software.

Hello listmenbers,

I am so happy to own a Acom 2000A (acquired second hand - 800 hours) plus Acom 2000SW (new) and Acom 2000S (new).

Right now I have the Acom 2000A controlling the Acom 2000S. But having two antennas for some of my bands I would like to control Acom 2000S from my computer. Can anyone point me to a piece of software to run under Windows XP
Pro that will do the job?

Best regards

OZ1CCM Kjeld

I had high hopes for TRX-Acom, which is part of the TRX-Manager suite of applications, but I believe is written by a 3rd party. Unfortunately TRX-Acom fails to support switching between multiple antennas for the same band segment. It also requires you to input antenna choice for each and every band segment, rather than by band, which is kind of annoying. I wish they could fix it, because TRX-Manager is otherwise a great application.

4617. Proper hookup FT-920

Yahoo group: acom-list (2010 — 2016)
Date: 2011-12-09 14:38:35 UTC
From: wvlymen
Topic: 4617 Message: 4617

What is the proper adjacent switch setting for the TX-GND connector of the Yaesu FT-920 that connects to the ACOM 1000 Tx-IN?

Also, is there a connection for the ACOM 1000 Tx-OUT from the FT-920...the manual says it is not absolutely necessary but has someone done it and how?

Thanks,
Bill, KN6V

You should be able to use either position, but the TR position will use
the transistor switching which is better for several reasons.
(faster, quieter,...)

Sorry - I don't understand what you're asking about here.

I think this is the best software out there for the ACOM 2000, and it controls the antenna switch:

http://www.m0yom.co.uk/

There are still some minor glitches, but the software is free. I use it every day with my 2000 (I don't have the antenna switch) which I run from a remote site, and it works great...much better than the factory software.

I'm happy to report to the list that TRX-Manager and TRX-Acom now fully supports the antenna switch and on-the-fly antenna selection via 10 buttons that have been added. Any manually selected antenna overrides the default for the entire band for the operating session, until a different antenna is manually selected.

FWIW, there's also a nifty SteppIR module that allows the SteppIR controller to also track the rig in addition to the Acom.

Bruce,

What schedule are you on? I will be selling my 1.5 yr old ACOM2000
after I work theHK)M dxpedition at the end of Jan. Am original owner.

Paid $6800. Asking 6000 and will include a pair of spare GU74B's. They
had been used in my Acom 1000 but output dropped off on 6M. They should
permit full legal power on 160-10.

Acom tells us to expect it to become available in the March/April time frame. All older 2000A amplifiers will work with it. Cost is expected to be in the $600 to $800 range.

Jeff,

If you have the optional Acom Switch (the 2000S/SW) you can have several physical antennas connected and automatically switched.

I wonder how ACOM will increase the agonizing slow 1200 baud rate of the RCU communications without a firmware change in the hardware? If it is just a matter of replacing an EPROM, that would be not be big problem for most users.

Mel,

The new RCU should work with every 2000A without changes in the main amplifier unit. That's why the baud rate have to stay as is. But the slow speed is a problem for the software developer of the new RCU only, and neither for the amplifier operation, nor for the user.

4635. Acom 2000A in Antarctica: help needed

Yahoo group: acom-list (2010 — 2016)
Date: 2011-12-28 10:04:29 UTC
From: Felix
Topic: 4635 Message: 4635

Hello,

this message comes to you from Neumayer Station, Antarctica (amateur radio club station DP0GVN). We have recently purchased a new Acom 2000A for use at our station. This setup has been recommended to us by the radio operators at Novolazarevskaya Runway (RI1ANR) who have been using an Acom 2000A for some time now with great success.

The amplifier has arrived recently in Antarctica by ship. We are, however, having problems getting it to work. We have installed the transformer according to the manual. No matter if we are using an antenna or a dummy load: after switching the device on, we always get error message "PLATE RF = 384V: SHOULD BE ZERO". We followed the handbook's advice, disconnected the radio and tried again after a few minutes, but the error message remains the same.

It is almost impossible to send the amplifier in for repair, as the time and expense for shipping would be horrendous. So we are very grateful for ideas which connections and components should be checked. Your help will be very much appreciated!

73 from Antarctica,

Felix, DL5XL, OP at DP0GVN

Hello,

I'd just like to let everyone know that the problem has been solved thanks to excellent service and support we have received from Acom in Bulgaria. A bad connection at the U27 multiplexer on the CPU PCB seemed to have caused the problem. I'd like to thank DJ1AA, DJ5AN, DJ6QT, DK3HV, DK7ZT, DL1YFF, and LZ1VB for making helpful suggestions and sending documents. I am overly impressed with Acom for locating the problem very quickly from data we provided - which is outstanding, particularly at this time of the year when almost everyone is on holiday. Stan, LZ1IU, has done a great job! If you worked or heard DP1POL on 30m CW tonight, you have witnessed the first hours of operation of our new Acom 2000A at Neumayer Station, Antarctica.

73 and all the best for 2012,

Felix, DL5XL/DP1POL,
Neumayer Station, Antarctica.

4637. Acom 2000A in Antarctica - Great Support

Great support is why I sold my alpha for my Acom 2K.

Alpha only wants to make a buck and doesn't care about helping the customer.

Now support is as close as Array Solutions 20 miles away.

I love my Acom 2K !

73-

From: wvlymen
Topic: 4640 Message: 4640

I have a FT-920. Can I run "barefoot" with an ACOM 1000 as it is designed to be connected for amp use? If so how is that doen? Does tha map have to be turned on or will it work with the AMP off?

Thanks,
Bill, KN6V

Just run it either turned off or in standby Bill, I have an IC7600 and
have had no problems running it `straight through'

Great Amp!

4643. Acom 2000A Ip alarm

Yahoo group: acom-list (2010 — 2016)
Date: 2011-12-31 18:10:47 UTC
From: N2TK, Tony
Topic: 4643 Message: 4643

Amp has been running fine for quite a while.

Yesterday when I turned it on it cycled through the time. When it came on I got an alarm "Bias too low at power on: -000V".

I hit the ON button on the RCU again. This time after a few seconds I got an alarm "Ip=520ma. Should be zero". The fan did not start either.

What I have done so far:

- Checked voltage on JP3:1 behind front panel -124V

- Unplugged JP2 on the HVSG board to see if that changed anything
- nope.

- Put in a new pair of tubes, just in case. No change.

Before I rip apart everything to see if can find out what happened, any ideas out there?

Tnx and Happy New Year.

N2TK, Tony

Tony,
Look at the files section of this forum. The zero bias problem is a "common" failure mode (not that there are many on an A2KA). There should be file that describes how to trouble shoot this problem and the likely culprit. I think its a cap on the control board. Good luck.

Tnx George. This is not the classic bias problem with the cap going bad on the power supply board. I had replaced the cap a few years back and the bias is fine.

This afternoon I checked the resistors mounted to the base of the tubes. They seem to be fine.

Since the fan does not come on right away I am wondering if this problem has something to do with the RCU? I had replaced the 22pf caps a while back that seemed were an issue in the early 2000A's. They became very leaky. The other reason I am curious about the RCU is that the alarm with excessive Ip when the amp first turns on before the tubes heat up. I don't understand how that could be happening unless it is a false reading.

Also checked C6 on the CPU board. I get 46K resistance from JP3:7 to ground. So I assume C6 is okay.

By the way was thinking of replacing both the input and output relays while I have the amp apart. The output relay is a piece of cake. But the input relay, that would take some work. I don't see a simple way of doing it because you need to get the board out which does not look easy.

Happy New Year

Tony,
Email the guys in Bulgaria they can probably point you in the right direction. I spent two weeks before Xmas chasing a problem in a Commander amp. They were never made to be taken a part after they left the factory. In order to get to the power supply caps almost every screw, front panel, rear panel, center divider, RF shield box has to come out. The first time you do it you think this isn't right; the second time you make a number of comments about the genealogy of the designer. Sorry I wasn't more help.

Tony,

There may be a socketed chip in your RCU. Sometimes, the pins get intermittent.

Try re-seating the chip in the socket and the problem may go away.

If not, Jay will be back on Monday and can assist you in troubleshooting it further.

-Bob

Hi Bob,

Tnx for volunteering Jay. J

I tried resetting the CU in the RCU. Also checked the remaining 22pf caps and replaced the last of them. Over the years they became leaky - only the blue 22pf ones.

W2SG got me rethinking about the Low Voltage Supply. Many of us have replaced C2, but what about the other caps? Well, sometimes a voltmeter only tells you so much. Drug out the scope. Found AC on the 48V and 24V lines on the Interface Board, JP3. 24V had lots of AC and very little DC.

Removed the Low Voltage Supply. Removed C15 and C14. Tested both. They are both leaky, especially C14.

Ordered caps today to replace all six large caps on the board since I have the board out. Went with 50V units for C14 and C15. Once I get them towards the end of the week will rebuild the board and check out the supply. Hopefully that was the problem.

Once I get this problem fixed will also replace Q1 the existing 500V in the HV Rectifier and SG Regulator with an 800V Mosfet.

HNY

Tony,
Look at the files section of this forum. The zero bias problem is a "common" failure mode (not that there are many on an A2KA). There should be file that describes how to trouble shoot this problem and the likely culprit. I think its a cap on the control board. Good luck.

4651. RE: [acom-list] Acom 2000A Ip alarm

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-05 01:09:43 UTC
From: N2TK, Tony
Topic: 4643 Message: 4651

Here is where I am at:

- Replaced C14 on the Low Voltage Supply. Now I get 24V without ripple. In fact I replaced C2, C14, C15, C22, C28, C29 since I gad the amp apart and I had new caps for this and one other cap had ripple on it.

- All voltages on the Low Voltage Supply seem normal now.

- Not sure why the one pictorial of the Interface Board shows +24VST on JP3:10. It seems more like a return line? Maybe I misunderstand the labeling?

Anyways I powered the amp. About 2 seconds after I turn it on from the RCU I still get the alarm Ic=500ma and the amp shuts off. I pulled the tubes and the same thing happens. The amp shuts off before the blower starts.

If I pull the plug on the high voltage transformer and turn on the amp I do not get the Ip alarm and the blower starts.

So it seems this has to do with the high voltage supply.

Any ideas?

Tnx

Hi Bob,

Tnx for volunteering Jay. J

I tried resetting the CU in the RCU. Also checked the remaining 22pf caps and replaced the last of them. Over the years they became leaky - only the blue 22pf ones.

W2SG got me rethinking about the Low Voltage Supply. Many of us have replaced C2, but what about the other caps? Well, sometimes a voltmeter only tells you so much. Drug out the scope. Found AC on the 48V and 24V lines on the Interface Board, JP3. 24V had lots of AC and very little DC.

Removed the Low Voltage Supply. Removed C15 and C14. Tested both. They are both leaky, especially C14.

Ordered caps today to replace all six large caps on the board since I have the board out. Went with 50V units for C14 and C15. Once I get them towards the end of the week will rebuild the board and check out the supply. Hopefully that was the problem.

Once I get this problem fixed will also replace Q1 the existing 500V in the HV Rectifier and SG Regulator with an 800V Mosfet.

Tony,

There may be a socketed chip in your RCU. Sometimes, the pins get intermittent.

Try re-seating the chip in the socket and the problem may go away.

If not, Jay will be back on Monday and can assist you in troubleshooting it further.

-Bob

Tnx George. This is not the classic bias problem with the cap going bad on the power supply board. I had replaced the cap a few years back and the bias is fine.

This afternoon I checked the resistors mounted to the base of the tubes. They seem to be fine.

Since the fan does not come on right away I am wondering if this problem has something to do with the RCU? I had replaced the 22pf caps a while back that seemed were an issue in the early 2000A's. They became very leaky. The other reason I am curious about the RCU is that the alarm with excessive Ip when the amp first turns on before the tubes heat up. I don't understand how that could be happening unless it is a false reading.

Also checked C6 on the CPU board. I get 46K resistance from JP3:7 to ground. So I assume C6 is okay.

By the way was thinking of replacing both the input and output relays while I have the amp apart. The output relay is a piece of cake. But the input relay, that would take some work. I don't see a simple way of doing it because you need to get the board out which does not look easy.

Happy New Year

From: Ron Castro
Topic: 4643 Message: 4652

Tony:

I would check R14 in the high voltage capacitive filter section (Page 9 of Appendix A in the Technical Supplement). I think that is the resistor where voltage drop is measured to determine plate current, and if it's open, the sensing circuit will see voltage that it would only see under high plate current conditions.

If that's not the case, the standard test procedure is to keep disconnecting components going backward from the tube plate connection towards the HV transformer and see where it stops shutting down. About the only other component that could be bad is the transformer itself, although I can't fathom how that would result in the plate current sensing circuit seeing a current draw...it would just pop the fuses.

Have you heard from the factory on this?

Hi Ron,

R14 is okay.

I tried the amp with all three plugs unplugged on the output of the HV transformer. No IP alarm unless I attach the HV plug. And this still is with no tubes in the amp.

So, the problem seems to be related to current sensing in the HV section.

I will copy W5OV at Array Solutions on this. Do you have any of the factory email addresses you can pass along?

Tony:

If you have high voltage probes, check the AC voltage out of the transformer and see if that matches what is shown on the schematic, just to make sure nothing is going on in the transformer that is not blowing fuses.

Wil's email in MA is K6ND@... and the folks at Array Solutions are at info@... (214-954-7140). You have some good diagnostic information and you should be within a few components of finding the problem!

Subject: RE: [acom-list] Acom 2000A Ip alarm

Here is where I am at:

- Replaced C14 on the Low Voltage Supply. Now I get 24V without ripple. In fact I replaced C2, C14, C15, C22, C28, C29 since I gad the amp apart and I had new caps for this and one other cap had ripple on it.

- All voltages on the Low Voltage Supply seem normal now.

- Not sure why the one pictorial of the Interface Board shows
+24VST on JP3:10. It seems more like a return line? Maybe I
+misunderstand
the labeling?

Anyways I powered the amp. About 2 seconds after I turn it on from the RCU I still get the alarm Ic=500ma and the amp shuts off. I pulled the tubes and the same thing happens. The amp shuts off before the blower starts.

If I pull the plug on the high voltage transformer and turn on the amp I do not get the Ip alarm and the blower starts.

So it seems this has to do with the high voltage supply.

Any ideas?

Tnx

Subject: RE: [acom-list] Acom 2000A Ip alarm

Hi Bob,

Tnx for volunteering Jay. J

I tried resetting the CU in the RCU. Also checked the remaining 22pf caps and replaced the last of them. Over the years they became leaky - only the blue 22pf ones.

W2SG got me rethinking about the Low Voltage Supply. Many of us have replaced C2, but what about the other caps? Well, sometimes a voltmeter only tells you so much. Drug out the scope. Found AC on the 48V and 24V lines on the Interface Board, JP3. 24V had lots of AC and very little DC.

Removed the Low Voltage Supply. Removed C15 and C14. Tested both. They are both leaky, especially C14.

Ordered caps today to replace all six large caps on the board since I have the board out. Went with 50V units for C14 and C15. Once I get them towards the end of the week will rebuild the board and check out the supply. Hopefully that was the problem.

Once I get this problem fixed will also replace Q1 the existing 500V in the HV Rectifier and SG Regulator with an 800V Mosfet.

Tony,

There may be a socketed chip in your RCU. Sometimes, the pins get intermittent.

Try re-seating the chip in the socket and the problem may go away.

If not, Jay will be back on Monday and can assist you in troubleshooting it further.

Tnx George. This is not the classic bias problem with the cap going bad on the power supply board. I had replaced the cap a few years back and the bias is fine.

This afternoon I checked the resistors mounted to the base of the tubes. They seem to be fine.

Since the fan does not come on right away I am wondering if this problem has something to do with the RCU? I had replaced the 22pf caps a while back that seemed were an issue in the early 2000A's. They became very leaky. The other reason I am curious about the RCU is that the alarm with excessive Ip when the amp first turns on before the tubes heat up. I don't understand how that could be happening unless it is a false reading.

Also checked C6 on the CPU board. I get 46K resistance from JP3:7 to ground. So I assume C6 is okay.

By the way was thinking of replacing both the input and output relays while I have the amp apart. The output relay is a piece of cake. But the input relay, that would take some work. I don't see a simple way of doing it because you need to get the board out which does not look easy.

Happy New Year

Tony,
Look at the files section of this forum. The zero bias problem is a "common" failure mode (not that there are many on an A2KA). There should be file that describes how to trouble shoot this problem and the likely culprit. I think

its a cap on the control board. Good luck.

The amp is working!

Tnx for all the suggestions and feedback from this reflector.

I got great help both from Acom and also Array Solutions. Both hit the nail on the head with the problem as did N6IE. Yes, it was R14 on the HV Filter board that opened. I made a terrible mistake of checking R17 which is okay. Stan from Acom sent me detailed instructions and drawings this morning. Jay and Bob from Array Solutions got involved and Jay called me last night and walked me through some testing which also pointed to R14.

The bottom line:

- The low bias problem caused the tubes to draw too much current which caused R14 to fail.

- I replaced all the large electrolytic caps on the Low Voltage Supply Board and also the SG Regulator Assembly Board since when I scoped the DC lines I saw ripple on a few of them.

- Replaced R14.

- Since I had the amp apart also replaced the vacuum relay for the first time. I use QSK all the time and I was getting some alarms that seemed to indicate a sticking relay.

Great support from Acom and Array Solutions on a 12 year old amp that has seen lots of use. And thanks again for all the feedback and help on the reflector, especially N6IE, N1LN, W5OV, W2GS.

The amp is back on the shelf in the basement. Only have the RCU in the shack.

73,

4657. Leaving ACOM 2000 in standby 24x7

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-07 13:23:33 UTC
From: Callum McC
Topic: 4657 Message: 4657

Because the amp is so quiet, I sometimes shut down my shack and forget to turn the amp off. The amp lives on top of it's flightcase under my desk with the control unit tucked out the way.

I use my amp most days but other than clocking up hours on the meter, do you think it's best to leave the amp on OPR / on STB - or OFF (at the controller)?

The reason for asking is that an acquaintance of mine lives for 6 months on a large motor yacht in the Pacific North West and once he switches all his electronics on, he leaves it on 24x7 and has very few hardware faults for a big vessel (with $300,000 of electronics).

I'm more curious than concerned!

Hello Callum,

I don't think it is better for the amp and its tubes to stay 24x7
switched on. It will not harm your Acom2000A if you switch it on a
couple of times during the day.

I always let the switch on the frontpanel of the 2000A in the ON
position and only use the RCU to switch the 2000A on and off. When I go
to bed or outside the house for more then a couple of hours, I switch
off the whole shack's electricity. I do this for many years and my 2000A
is 7,5 years old.

Letting everything switched on 24x7 certainly is'nt good for your
electricity bill ;-)

All the best and 73!

From: Callum McC
Topic: 4657 Message: 4659

Thanks for your input Hans.

I never switch the ACOM off at the mains, only the RCU. I will remain happy with my procedure now that you have explained yours. Good work. Tnx.

73.

C.

From: N2TK, Tony
Topic: 4657 Message: 4660

Hi Callum,

My 2000A is on most of the time during the winter months. I figure it doesn't hurt anything and if I want to work someone, especially on the low bands I don't have to wait for the amp to cycle.

In the summertime I usually have the amp off from the RCU. But since my amp is down in the basement I almost never turn off the main OFF-ON switch.

73,

N2TK, tony.

From: acom-list@yahoogroups.com [mailto:acom-list@yahoogroups.com] On Behalf Of Callum McC

To: acom-list@yahoogroups.com
Subject: [acom-list] Leaving ACOM 2000 in standby 24x7

Because the amp is so quiet, I sometimes shut down my shack and forget to turn the amp off. The amp lives on top of it's flightcase under my desk with the control unit tucked out the way.

I use my amp most days but other than clocking up hours on the meter, do you think it's best to leave the amp on OPR / on STB - or OFF (at the controller)?

The reason for asking is that an acquaintance of mine lives for 6 months on a large motor yacht in the Pacific North West and once he switches all his electronics on, he leaves it on 24x7 and has very few hardware faults for a big vessel (with $300,000 of electronics).

I'm more curious than concerned!

Callum

You should contact Acom and ask for it. They will need your amp
serial number. I did and got a CD from Bulgaria containing schematics
and voltage charts plus a lot of other info.

4664. Acom 2000a: "Screen voltage on before time out over" message during startup

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-09 03:37:10 UTC
From: James
Topic: 4664 Message: 4664

Dear Acom 2000a experts,

I am the enthusiastic new owner of a used Acom 2000a.

I consistently receive this error

("Screen voltage on before time out over")

after the timer counts down and hits zero.

I have run the memory reset, tried this a half dozen times, and I have removed the anode caps of both tubes in an attempt to remove the tubes as the source of error. Same error message.

I have heard from DL2CC about the possibility of a burned out resistor and have also read about C2 failing.

If you are familiar with his failure mode and the likely components to inspect - please let me know, and if possible reference a picture showing the board and component to inspect.

Thank you in advance for your help!

Sincerely,

Jim Nitzberg WX3B

Hi James

I had a similar problem....and with help of Acom..I find out was one of the tube.

Please read message exchange

Good luck

i5NPH

Natale
Hello Natale,

The results (18V) confirms my suspection. Either tube has an internal leakage or vacuum degradation and the anode voltage leaks some current into the screen grid circuit and increases the off-state voltage. The protection trips when the voltage exceeds 20V and it is just at the threshold now. You may check the ceramic surface between the anode and the screen grid for any contamination but most likely the problem is inside the tube. The remedy is tubes replacement.

Please see attached tubes replacement instruction. Please note that the tubes should be with close characteristics and that the idling current should be re-adjusted after the replacement (see the attached picture).

Should you have further questions please feel free to contact ACOM again.

Hi Stan

Thanks for your answer:

SCREEN-V during Stand By mode is 18V
SCREEN-V during Operating is 332-334 V

Waiting suggestion

73

Natale

Subject: Screen grid voltage in ACOM2000A

Dear Natale,

Please enter the MEASURE menu and copy for me the SCREEN-V during Stand
By mode - it should be below 15V. Then go to OPER mode and copy the value
again - it should be 340V (330 to 350 is acceptable).

My expectation is that the STBY voltage is nearly 20V where a protection
trips. Normally this requires tubes replacement.

Please give me the serial number of your amplifier.

73 Stan LZ1IU

Topic: 4664 Message: 4666

I would also suspect the tubes. Back about 12 years ago, when I got my 2000A, the amp immediately faulted with an error related to the screen voltage (can't remember which message, but not the same as yours.) Krassy deduced the cause as a bad tube and told me that the screens in these tubes are very delicate and sometimes get damaged in shipping.

Unfortunately, you can't just stick in a new tube. The tubes should be matched and there's a somewhat involved process for setting the bias. In the old days, Acom wasn't comfortable with owners doing it, so I had to bring the amp to Krassy for repair. Now the instructions for replacing the tubes are in the file section of this Yahoo group and you can do it yourself.

I should mention that Krassy went out of his way to make the repair easy for me. I had a conference to attend at a hotel in Boston, which is a couple of hours from my QTH and an hour or so from his. I brought the amp with me and Krassy picked it up at the hotel, brought it back to his place, then delivered it back to me, repaired, by the end of the day. Quick and painless for me.

Hi Dick, Natale and other Acom 2000a enthusiasts,

Thanks to a good friend (N3KS) I borrowed a nice pair of new tubes this evening, and now have RULED OUT the tubes for causing this

"Screen voltage on before time out over"

message. It failed identically to how it failed with the old tubes.

I plan to follow-up with Acom later this week and see if there are any other good guesses.

Thanks for your thoughts and suggestions.

73,

Jim WX3B

Me too.

Using a rather early one, there will be problems later on. So I'm interested in a source to get access onto the technical manual also.

Guys,

I sent Bruce what I had because he bought the 2000 from me. I'm not
sure about copyright issues and won't distribute it to anyone else.

Some or most of the information may be available in the ACOM reflector
"files" section,

The tech CD for each amplifier is available from your Acom dealer - usually just for the cost of shipping.

Me too.

Using a rather early one, there will be problems later on. So I'm interested in a source to get access onto the technical manual also.

Brian, Can you POST it Somewhere, I'd like to have that myself here?..
I Could put it on the Back side of my QSL.NET page if you like Also?.
THANKS!..

This coming Thursday I will be taking delivery of my very first ACOM, a 2000A. Can anyone summarize the wisdom that has come from this group over the past twelve years and almost 5,000 messages?

What have you as a community learned that can possibly help me as I introduce myself to my new ACOM. Do's, not do's and don't ever do's.

Thanks for whatever knowledge you can share.

Hello Dick,

Welcome to the Acom group!

You made a very good choice.

What are your favorite modes?
Are you participating in contests?
Do you like ESSB?
What is your exciter and what kind of antennas are you using?

73!

I think the wisdom can be summarized as: you made a great decision Dick, congratulations! The amp is very well protected so no do's or don'ts immediately come to mind. The amp's fault detection system is sensitive but trustworthy - if it consistently says there's a problem, you need to troubleshoot and not ignore. If you ever do have a problem, troubleshooting help is easily obtained on this reflector and directly from Acom USA, Acom Bulgaria, and Array Solutions.

Dick,
I will add my vote to the " you made a great decision..." assessment. I have only owned my Acom 2000A for about three months now but what a three months it has been. This is simply a beautifully built, quiet, capable piece of equipment that flat out works!

Before my Acom, I had an Alpha 9500 (three actually, each with unique and different "issues"/failures) over a period of about 18 months and in the end the only thing I liked about the 9500 was the automatic tuning of the amp. I decided to try an autotune amplifier one more time and with great trepidation I ordered the Acom. I needn't have worried, this amp flat out works! No more unexplained faults, no more incidents of smoke filling the shack (happened twice with Alpha number 2), no more screaming fan, no more vacuum relay that can be heard across the house, no more banishment to the "three minute penalty box" a phrase that was attached to my continually have to wait for the amp to re-set after a "fault" shut it down in the middle of a qso.

No fuss, no muss, the Acom is just a beautiful thing. I think this may be the nicest piece of ham gear I own!

Hello Dick,,

Congrats on your purchase of a 2000A. I have had mine for 6 or so years, and it has been fantastic.

Feed it with a good clean supply of 220 vac, and it should give you excellent service. Occasionally I will switch mine to a wrong antenna, and it will fault off due to high vswr. However, nothing I ever do to it seems to harm it; it just keeps on ticking.

I'm with George. Owner for 6 years too. I will say though that I can feed from a not-so-clean generator, or super-clean utility power and it seems to deliver the same results.

And of course, if I do something dumb (which is quite normal for me!), it bleeps at me and flashes a red light.

Best toy I've ever owned.

(And when you are bored with it, download James's fabulous ACOM 2000 remote software from www.m0yom.co.uk)

Dick

Welcome to the club my 2000A has been in service now over 9 years with 8500 hours and on its second set of tubes, it has been one of the best purchases I ever made in ham gear . I also owned 1000 also both of these amps have worked without failures causing me any expense for repairs. Remember to clean the filter every 6 months and amp should last a lifetime . Factory support is just email away for any tough technical question that your dealer can not answer .

Dick,

Have had the 2000A for 12 years. It has seen a lot of operating. I have had a few problems with it. But Array Solutions and Acom in Bulgaria give top notch service both email and over the phone.

I have so much faith in the amp that I don't even have it in the shack. The RCU is in the shack and the Amp is in the basement on a shelf where I have all my cabling, and grounding equipment.

You made a good choice with the 2000A.

73,

N2TK, Tony

One of the best pieces of equipment you will ever own !

Amen to all the comments about the Acom !

You will notice no one is complaining or having unresolved issues or bait and switch issues with Acom service.

Alpha just doesn't stack up to the Acom in so many ways mentioned through out these threads.

Enjoy the power and performance of the best !!

From: Damon Cassell
Topic: 4681 Message: 4681

While I wish I could say it's a 2000A; in this case my new amp is a model 1011. My antennas are just wires, so this amp is a nice addition but not overkill. The unit was purchased from Array Solutions which, as everyone knows, was very responsive and answered all my questions before I pulled the trigger. The amp arrived in perfect condition and I had it integrated into my station easily, thanks to the straightforward manual.

This is my first linear amplifier in 22 years of being a ham. I could have paid half the price for an AL-811 and had the same power output, but the outstanding reviews and unquestionable quality difference steered me to Acom. The reputation of both Acom and Array Solutions in resolving customer issues was also a factor.

I'm happy to report my amp powered up perfectly and has been on the air with no difficulty whatsoever in a very short period of time and I really enjoy operating it. I have one question for the list which is a general one that probably applies to all tube type linear amplifiers. The manual warns that frequent cycles of turning on and off the amplifier can shorten tube life. How big of an issue is this? On weekdays I might operate several times for an hour or so in the evening. On the weekends I might operate 2, 3 or 4 different times during a day spanning the morning through evening. Am I better off leaving the amp in standby or can I shut it off and turn it back on 2-3 times per day (a few days per week) without significantly impacting tube life? Any advice appreciated.

Damon,

Good question, I would like to hear further debate on the topic from others. Most people here switch the amp on and off anytime they please. Others apparently switch it on in the morning and off at night using "one cycle". I'm still not quite sure exactly what I should be doing. Mine's been on all day and I still haven't used it - but I might need it later so I'm keeping it on now.

For reference, the stand-by current drain appears to be negligable.

Callum.

Callum, thanks for the comments. How did you measure standby current drain
and from a standby current perspective, what would an equivalent device be?
Also what model do you have? I have a few desktop computers in the house
that are on 24/7. That probably skews my power consumption here anyways.
But I was curious about this.

Hello Damon,

I have an Acom 2000 and I watched my utility power meter change when I switched it off. The meter measured and re-displays every 5 seconds. It's about 100 watts or so.

I have just made another check and from a cold start, power consumption is considerably higher due to the tubes having to be warmed up. About 500 watts.

Callum

4685. Powering up the Acom amps.

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-15 20:24:59 UTC
From: georgek5kg@aol.com
Topic: 4685 Message: 4685

Damon,

I have a 2000A and a 1010. Previously, I had an Acom 1000, which I sold and replaced it with the lighter weight 1010.

Here is what I do with respect to powering them up.

2000A - I generally leave the main power switch on unless I am going away from the shack (house) for a few days. When I am ready to operate, I turn on the amp from the control head. If my usage is going to be off and on over the weekend, I will leave it on all day. At the end of the day, I will turn it off at the control head, but leave the main power switch on.

Acom 1010 - I turn the amp on and leave it on for the weekend or a contest. I generally will turn it off when quitting for the day. I take the 1010 on dxpeditions where there generally is no air conditioning and, therefore, there is humidity. I leave the amp turned on for the entire duration of the dxpedition which may be a week or two. I found that with an old tube amp (AL-572) that if I turned it off overnight that moisture would condense on the tubes which would create arching (and fuse blowing) when I turned it back on in the morning. I learned to leave that amp on for the duration of the dxpedition, which I now do with my 1010 since it is also a tube amp. In fact, I leave all equipment, including my K3, turned on for the entire duration of my dxpedition operations.

There is a caution about powering up the 1010 that I want to mention, as it may be the same in your 1011. That is, when the amp powers up, it comes alive in the "operate" mode. With my 1010, I watch it closely when I am waiting for it to "come alive", so I can turn the Operate switch off until I am ready to apply RF and tune it.

I hope this helps.

Hi, Hans.

I am primarily a RTTY operator with SSB coming in second.

I am fond of RTTY contests which is where I have broken my old reliable AL-1200 twice.

I am not familiar with ESSB.

I am using an Icom IC-7700 as an exciter into a Hy-Gain TH11DX, Cushcraft 40-2CD, W7INN inverted-V and Gap Voyager DX-IV.

Thanks for the welcome, Barry. As I recently mentioned to Bob Naumann,
I'm not interested in a 2KW amp, just a set-it-and-forget-it 1.5KW
transceiver. When I get my AL-1200 back from Ameritron (I don't like
the sizzling sounds coming from the final cage), I will probably keep it
as a SSB backup and sell my venerable old Drake L-4B.

Thanks, Bruce. I don't think ACOM could wish for a better
recommendation than that. Thursday can't get here soon enough for me!

Thank, you Phil. MTBF is important to me as I am now getting ready to ship my AL-1200 off for its third round of repairs. Ameritron made a good amp, but it just can't handle full-power RTTY contesting. That is where I am hoping my ACOM will shine.

Hi, Tony.

Thank you for the vote of confidence for the 2000A. That kind of reliability is exactly what I am looking for. I am glad I didn't go for the big Alpha box. I am hearing nothing but problem reports regarding it.

Thank you, John.

Along with the exemplary words regarding the 2000A, I am also hearing nothing but kudos for the people who stand behind the gear. That is equally as important as the equipment itself.

One of the better functions of the Acom 1000. You can program it to stay in stand-by instead of operate when tube is heated up after 150 sec.

4695. 2nd Acom 1000 in the shack

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-16 04:48:05 UTC
From: Philippe ON4VP
Topic: 4695 Message: 4695

Hello group,

Like to (re)introduce myself. I've been an Acom user since 2001. I've owned the Acom 1000 for over 5 years. Sold it in 2006.
Last year, mid 2011, I was looking at a second Acom 1000 again but I've tried the SPE Expert 1K-FA that I found second hand in mint condition. However fan noise and transformer hum made me rethink my decision together with the fact that over 80 out of 1500 amps sold suffer from faulty rx/tx relais.
In my opinion the 1K-FA is made for 600 watt transmissions where it shines. 1KW is possible but puts stress on the design. Two best things were the 4 antenna inputs and no heating or tuning when spotting dx. Nevertheless I sold the 1K-FA and ordered the Acom 1000 again. I missed it to much. The exciter is a FT-950, antennas Optibeam yagi and dipoles for low band.
Info on qrz.com.

73, Phil ON4VP.

Hello Dick,

Thanks for your reply; in this way I can give you a targeted response. I use my Acom2000A for 7,5 years no and still am a very very happy user!

1. When you do primarily RTTY I would advise to install the optional ventilator.
On my internetsite you can see some photo's of how I did this:
http://www.remeeus.eu/ham-radio/linear-amplifiers/acom-2000a-ebs-modification-and-installation-of-the-optional-fan.html

I mounted the Papst 4412 F/2GLL, but in the meantime I found an excellent alternative for this fan: the amazing NoiseBlocker M12P: http://www.noiseblocker.de/en/Multiframe120.php I installed this fan in my other amplifier, with very good results.

2. I don't think there is a need to do the EBS-modification as you do primarily RTTY.

3. The IC-7700 has no ability to use the KEY OUT function of the Acom2000A, but this feature is mainly interesting when you do a lot of QSK. I used the IC-7700 as exciter for the Acom2000A for 2,5 years and I did not notice any problems, like power spikes. The connection between the RELAY of the IC-7700 and the KEY IN on the Acom 2000A is enough for pleasant operating this setup.

4. The Acom2000A has the ability to handle SWR up to 1:3,0. However I notice that the protections of the Acom2000A sometimes are a little bit over-sensitive, not only in case of bad SWR but in other situations too. Never mind; you will learn yourself what is and what is not possible, like all the other amplifiers ;-)

5. The service of Acom is great! During 7,5 years using the Acom2000A I asked them a lot of questions and they always give a very kind, very fast and very comprehensive response, sometimes even with drawings, pictures and photos; all my compliments go to Acom!

6. I still use the same GU74b tubes after 1,896 hours on the airtime and still with +/- 15dB gain!

Enjoy your 2000A and let me know if you have any questions.

All the best and 73!

Thanks for the follow-up, Hans. I made sure to have the factory fan installed by Array Solutions before the unit shipped. I've burned out my AL-1200 twice and I don't want to take any chances, even with a workhorse like the 2000A.

Best DX,

Dick

Hi,

Keep output power max 800W when you run RTTY contest.
Monitor Tube temperatures, it should be under 80C

You need extra fan and enough RPM for it, otherwise temps will raise.
1500 W is possible but why take the risk.

My tubes seen over 4000 hours
Power gain is 15db and temp variation between tubes are under 2C.

Keep it cool.

Topic: 4672 Message: 4699

Tomi,

I think that this is exaggerated! Under 80C would be fine if the finals were solid state. But according to the specification, those tubes are OK up to 250C. I won't be concerned if I see 100-120C during a contest. And respectively would almost double the proposed 800W.

Hi Val

It's perhaps exaggerated but it's how I run RTTY contests.
Extra 3db is not so important to me.
I think it wont last long if used at full power in RTTY contest.

Why keep the temp so low? I thought the temp cutout is at 130C? I have never seen an issue with running 1500W on RTTY.

Got over 6K hours on the first set of tubes.

N2TK, Tony

Hi,

Keep output power max 800W when you run RTTY contest.
Monitor Tube temperatures, it should be under 80C

You need extra fan and enough RPM for it, otherwise temps will raise.
1500 W is possible but why take the risk.

My tubes seen over 4000 hours
Power gain is 15db and temp variation between tubes are under 2C.

Keep it cool.

Dear Dick,

I can just second all the nice things said about the Acom 2000A (bought mine secondhand a few months ago).

If you have a number of antennas I can recommend Acom 2000S and 2000SW. Not cheap but very good and really nice to have.

Best regards

OZ1CCM Kjeld

4704. What's That Noise?!

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-20 03:30:55 UTC
From: Dick Flanagan
Topic: 4704 Message: 4704

My new 2000A arrived today and I'm in the process of getting to know it. The first thing I noticed was how loud the tuning motors are! The first time the amp tuned itself the noise made me jump, the dogs bark and my wife to come in from the other room asking what that noise was!

Is it normal that the tuning motors should be so LOUD!

Hello Dick,

After the warming-up period of the 2000A the motors make a loud noise.
It is a very strange noise. That's correct. It is quite normal and
nothing to worry about.

What you wrote in your message sounds very familiar to me. My wife had
exactly the same reaction when she heard this loud noise for the first
time; it really scared her.

However, this is the only loud noise the 2000A makes. The rest of the
tuning is (relatively) very silent. My fans are whisper silent, so yours
must be too.

Please keep us informed about your further experiences; we hope to be of
help

Thank you, Hans (and you too, Hank). Having never operated a 2000A
before the noise really got my attention. Now that I know it is normal,
I will simply expect and ignore it.

Thanks again to you both.

Dick

Watched the videos. Indeed a lot of noise ! Now the real question is why only at startup and not every time when tuning is needed (according to what I read while tuning this is not the case)?

It sounds like a mechanical reset procedure of a big gearbox...
Autotuning is fine and great, but the Acom 1000 still is the most silent amp on the planet ;-)

I was thinking, why Acom never made a 1KW version with single tube but with auto tuning for a competetive price?
I think they would find a lot of customers for it if price would settle between Acom 1000 and Acom 2000a (f.e. 3000 euros)

On start-up, the motors test their full motion and make the most sound.

The closest you might get to that during normal operation is QSY from 160 to 10m where they move the most.

Adjacent band QSY: 160 to 80, 80 to 40, 40 to 20, etc. does not make as much sound.

I'm no mechanical engineer but my guess is that's exactly what's happening. At start up, the stepper motor positioning is unknown so it must go through a recalibration procedure to a known starting point, so it slews a sufficient amount so the end point is definitely reached. With the way the 2000A reliably performs year after year, that's the sound of music.

I doubt they would be able to cut the cost all that much by eliminating one tube and downscaling the power. A 1KW version probably wouldn't end up being cost effective, using the current costly electromechanical design.

My new 2000A arrived today and I'm in the process of getting to know it. The first thing I noticed was how loud the tuning motors are! The first time the amp tuned itself the noise made me jump, the dogs bark and my wife to come in from the other room asking what that noise was!

Is it normal that the tuning motors should be so LOUD!

> What's That Noise?!

It's the sound of stepper motors. Stepper motors work by advancing the stator field in discrete increments, producing a click as the rotor snaps over to its next position. A sequence of these steps at a high rate produces an sound in the audio range, which is what you are hearing - quite normal. Steppers are somewhat less precise than a good servo, which would also be quieter, but they don't drift and are way less trouble and expense. At startup the 2000A is simple flexing its muscles to verify that not is calibrated and working properly.

On SSB, I normally TX a brief "uhh" to make the amp retune after a band change. However, "BEAR!" sounds a much better way.

The back of the amp shows 3 muffin fans. It would seem that this can't
be an acoustically quiet amp.

The single muffin fan on the KPA-500, even at the lowest fan speed
steps, interferes with weak sig CW using earphones. This was supposed
to be a fan selected for its low noise.

Three fans have to be louder.

4739. Low Gain <=> help needed

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-29 18:19:18 UTC
From: Thomas Herrmann
Topic: 4739 Message: 4739

hello,
at ACOM2000A more often I get displayed "LOW GAIN" after some minutes of operating and switching into STANDBY modus.
Manual says to check koax between TRX and PA. In my case, I can't find any mistake with the coax. To be sure I exchanged the coax between TRX and PA but still get the error message.

Any hints what to do, please ?

73 de Thomas, DL1AMQ.

The exact same reason why I sold my Expert 1K-FA and got a second Acom 1000 instead.
I loved both the fact that I was instant on and no tuning but couldn't bear the noise of the 7 fans.

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-29 20:34:42 UTC
From: Hans Remeeus
Topic: 4739 Message: 4741

Hello Thomas,

The gain is calculated, the value will depend on the input and output power.

With this message the amplifier will switch off if the input power is
too great and the output power too small. It is possible that the action
is as described (worn out tubes) or problems in the circuits for
measurement and their calibration.

Interface PCB
RP4 - fwd - output power
RP9 - inp - input power

Please try the AUTO TUNE function (in the sub-menu while in the MAIN
menu) a few times. This could help; it did help with my Acom 2000A...

4742. HV Capacitor Cb2.2 Failed

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-29 21:11:12 UTC
From: jim balls
Topic: 4742 Message: 4742

Hi all,

I Was about half an hour away from the start of the BARTG Sprint contest when I powered up the ACOM 1000 which is about 3 years old, after about 30 seconds of the warm up period I heard a loud crack and and error message on the display stating a safety circuit shutdown.

Upon investigation I found the capacitor Cb2.2 a 2.2n/10KV ceramic disc had flashed over blowing a small section from the side and causing the capacitor to go short circuit, This capacitor is the first on the HV supply side of the RF choke just after the HV safety crow bar.

I notice on the original schematic that these caps are rated at 6KV not 10KV, so I'm thinking maybe an upgrade has already been done in the manufacture process.

Looking back through the site I see this has happened before with no real reason for the failure orther than a weak capacitor maybe

Anyway I would like to know if anyone knows of a source of these HV ceramic disc caps at a reasonable price?

Thanks

Jim M0CKE

Hello Hans,
many thanks for Your hint.
I did "AUTO TUNE" often during last few years and used resulting "USR" settings instead of "DEF(ault)" in OPER(ation) modus.

Don't know why, but now (since ??) there are back DEF settings. Doing AUTO TUNE now, I hear the motors moving and get as result "DEFAULT: CHECK VSWR".
Checking VSWR, I get 1:1.3 what is looking well for me, but I still have DEF settings.
Don't get USR settings at all.
So, it seems that either tuning procedure or readings by software is wrong.

Anyone else had such ACOM2000 behavior and has a solution, please ?

Jim

Had a failure here too, where two of those capacitors failed. The amplifier was quite young at the time.

It caused failure of other nearby components and I had to return my amp for attention, via Vine.

The 6kV rating should be sufficient for a line that has about 2800v on it, so perhaps the components were not up to spec.

Regards

John G4ZTR

4748. Acom 1011 . IP Failure

Yahoo group: acom-list (2010 — 2016)
Date: 2012-01-30 15:42:06 UTC
From: Davide Pisani
Topic: 4748 Message: 4748

Hello everybody,
I'm reporting an IP-Failure on my acom1011 amplifier.
When I try to transmit, the "IP" led and the "F" led turn on and the amplifier goes on stand-by.
This will happen again and again and again.

When I noticed this failure, one month ago, it was a rare event...so I thought it was RFI on the cables.
Day by day this rare event turned into a much more regular event and now I can't use it at all.
I have to say that, when I can operate without this IP-Failure the amps is working good.

What can be the problem, in your opinion? I'm suspecting one of the tubes is not properly working.
best 73!
Davide IZ8ESX

PS: sorry for my bad english, I know I have to improve it :)

Not very likely. This past November Adobe announced that they would be phasing out Flash for mobile applications and moving to HTML5, the standard that replaces it and then some. They have already released a conversion tool for Flash content. Flash is a CPU hog, and has not kept up with audio and video standards. Flash is very entrenched, but it seems that even Adobe can see the handwriting ?

I couldn't tell you what the specific problem is but I would give two pieces of basic advice. If you come across a fault, assume the worse and check it out, an email to the manufacturer/dealer may be all that is required. Secondly until you figure out what the problem is avoid using the equipment as at some point it will probably lead to catastrophic and unpredictable failure.

Just my $ .02 worth based on my own expensive mistakes.

Thank you!
I'm going to send it back to the dealer.
I've seen on a forum that the ACOM 1011 could suffer for tubes failure, I'm sure the dealer will help me solving this problem.
I will let you know. 73!

good evening I have some info to change the valve to acom1010. On ebay there are many listings gu74b/4cx800 NOS. I read on several forums that since it's NOS tubes, must first be preheated to prevent it from breaking. I wanted to ask if buying a NOS GU74B simply leave the acom1010 lit for 10 hours to do the warm-up or you have to do a special procedure?
someone has bought gu74b/4cx800 NOS? hello all

ciao Davide , grazie per la rispota .
Questo link lo avevo gia visto . il problema che ho trovato solo questo link , quindi vorrei essere sicuro che il preriscaldamento del tubo va fatto solamente lasciandolo acceso per 5 ore.
quindi chiedo se qualcuno ha gia usato questo metodo.
ciao grazie

Hello David, thank you for rispota.
This link I had already seen. The only problem I found this link, so I want to be sure that the preheating of the pipe should be done only by leaving it on for 5 hours.
so I ask if someone has already used this method.
Hello, thanks

Try this link. I used this procedure on 3 NOS tubes and it
seemed to work fine:

Concerning new tubes "pre burning", I can tell you that it can be of use with old tubes which have been on shelf and never heated for longer than several (say 5) years. The pre-burning procedure involves 1-2 hours "heater only" mode (air cooling is required also in this period). This will improve the vacuum depth. Two useful effects can result:
a) The probability for an internal flash (voltage break-down) is minimized. This rarely happens with this tube. For maximum protection, the anode voltage should be applied in steps of 25%,keeping for 15 minutes
b) The cathode surface is saved from heavy ion "bombing" which could irreversible ruin the cathode emitting capability otherwise.
Practically, when using a new tube first time, it is useful to let it run for 1-2 hours without going to OPER mode (I have seen recommendations for up to 10-12 hours but this seems unnecessary to me). The amplifier is properly protected against tube flashes, so disconnecting the high voltages for this period is superfluous. Even though a flashover could occur, the amplifier will protect itself and also the tube and you can usually restart the procedure. Flash-overs quickly improve the vacuum and the tube could fully restore after that. Should flash-overs happen continuously, such tube is 100% junk and even 24h with only heater applied would not help. The important issue is not to draw any current from the cathode at least one hour after having applied heater voltage for the first time after a years-long pause.
The whole procedure could be skipped if the tube has been in use in the latest three years. If you are not sure about the tube history however, it is best to run this procedure. It would not harm but if you would fail to do pre-burning for a tube which has been for long on the shelf, you risk to lose it - any procedure would be ineffective after current has been drawn from cathode under poor-vacuum conditions.

Subject: [acom-list] Re: Degassing and gettering a tube

Fully install the tubes and turn on the amp. Let it sit in standby for
5-6 hours. Then go to operate and run the amp in intermittent service
(a nice CW rag-chew) at half output power for 30 minutes, and that's it
for gettering. To complete the job - run the tube replacement bias
adjustments per the amp's tech manual.
The common failure in a tube with some gas is an anode arc-over.
However, since the DC anode voltage in these amps is substantially lower
than the maximum allowed for the tube, and in standby the control grid
is biased WAY off, and the screen voltage is zero, the chances of an
anode arc are negligible. The tube would have to be total junk to arc
under these conditions. I would be interested in hearing from anyone
who has ever had an anode arc-over bringing up a NOS GU-74b in an ACOM
amp.

A not unrealistic alternative is to buy a used (or NOS) socket on eBay,
and with some air blowing up through the socket simply power the
filament of the tube in question at full filament voltage for a few
hours. You cannot simply clip-lead on to the filament pins and power
the filament. Without the socket and cooling air the filament seals
will be destroyed in short order.

ciao Davide , grazie per la rispota .

Questo link lo avevo gia visto . il problema che ho trovato solo questo link , quindi vorrei essere sicuro che il preriscaldamento del tubo va fatto solamente lasciandolo acceso per 5 ore.

quindi chiedo se qualcuno ha gia usato questo metodo.

ciao grazie

Hello David, thank you for rispota.

This link I had already seen. The only problem I found this link, so I want to be sure that the preheating of the pipe should be done only by leaving it on for 5 hours.

so I ask if someone has already used this method.

Hello, thanks

From: Dick Flanagan
Topic: 4752 Message: 4758

When I switch to a new band on my 2000A, I adjust the drive until the first red LED lights (1.6 KW) and then I back off just until the LED goes off.

I just tried that on 17M (18,100 kHz) and was unable to get the first red LED to light (1.6 KW). The output indicators would go up to 1.4 KW, but any increase in drive would not increase the output any further.

If I continue to increase the drive power I will eventually get a drive fault, but the output (as measured by the output LEDs and an external watt meter) does not go above 1.4 KW. SWR is low and none of the reflected LEDs light.

All other bands seem to operate normally. Is there anything unique about 17M and the 2000A?

The 2000 comes with presets that may or may not match you antennas. You need to autotune the amp on each segment to match your antennas, these user presets are then saved and used in the future.

Well, the anomaly has been corrected, but not really explained....

I went out to check the tuning. First I fired up on 18.100 as I had done before to verify the anomaly was still present. The remote showed I was using a USR preset for 18.000-18.150 and I was again unable to indicate more than 1.4 KW output.

I went through the AutoTune procedure and was than able to get full output from the amp. While re-tuning obviously corrected the problem, it does beg the question as to why did the amp go out of tune? The antenna did not change and the SWR was very low both before and after the re-tuning.

What I don't recall is what frequency I used for the initial 17M tuning. Should I have to go through the AutoTune procedure for each frequency segment? In other words, now what I have tuned the amp for the 18.000-18.150 segment, if I want to operate on 18.200 should I expect to have to re-tune for the 18.150-18.300 segment?

Is it common for the amp, itself, to go out of tune requiring re-tuning? I have only had the amp for a few weeks and I still have a lot to learn about it. I appreciate everyone's help.

Hi,

Sometimes even with an antenna that is perfectly matched for a specific band can change in impedance due to external factors. Rain, icing, fog, nearby structures, etc... can make the impedance shift a bit resulting in the amp that needs to be retuned.

I learned never to take it for granted that all my antennas remain tuned all the time. The goal here is to always observe every antenna before operating.

I'm not sure this is what happened but it is one of the possible explanations for your issues.

I periodically retune my 2000A, especially when I begin seeing the drive lamp flicker as I increase power. Retuning seems to cure that.

After I retune it, she always breaths a sigh of release, and gives me a big thank you!

> Is it common for the amp, itself, to go out of tune requiring re-tuning?

No. If your amp is new, it's most likely that you didn't tune the particular frequency you're using or some external factor changed the impedance of the antenna after you tuned the amp for it.

Note that SWR does not tell the whole story when it comes to tuning. Even resonant antennas present a unique combination of capacitance, inductance and resistance (i.e., impedance) that must be matched by the amp.

Also note that it is, in fact, possible for the amp to go out of tune, but this would be more likely if the amp is used and/or has a lot of miles on it. I know of two possible causes:

1. If the nut that secures the plates of the Load capacitor loosens up, the momentum of the relatively heavy plates can cause them to swing past the point where the stepper motor stopped (dragging the stepper motor with them.)

2. The detents in older stepper motors can wear, again causing the plates to miss the target position.

The symptom is that you tune the amp for a particular segment, then go off to another segment, band, antenna, etc. When you come back to the exact same frequency, the antenna is no longer tuned. Typically, you can't drive the amp to full power, which is what you found on 17m. This happened to me on all bands, and on advice from the factory I ended up replacing both stepper motors. In the course of doing that, I discovered that the real cause was the loose nut on the Load plates, described in #1 above.

Hello everyone,
regarding the procedure described by LZ1IU for replacement of the valve on the ACOM1010, wanted to ask another clarification.
When I turn the ACOM1010, after a short heating time, automatically switches operated mode. So that means that time is giving me high voltage to the valve? If I have to getting the valve, then wait 5/6 hours stadby before going to operate, how can I avoid passing in automatic mode made to avoid giving high tube voltage and then create his own failure?
Or even if the amplifier will operate in nothing happens, but it's important not to convey?
I await your response
73 IZ8HUJ
IZ8HUJ@...

Ciao a tutti ,
riguardo la procedura descritta da LZ1IU per la sostituzione della valvola sul ACOM1010 , volevo chiedere un'altro chiarimento.
Quando accendo l'ACOM1010 , dopo un breve tempo di riscaldamento , passa in automatico in modalità operate . Quindi significa che in quel momento mi sta dando alta tensione alla valvola ? Se io devo fare il condizionamento della valvola , quindi aspettare 5/6 ore in stadby prima di passare in operate , come faccio ad evitare che passa in automatico in modalita operate per evitare di dare alta tensione al tubo e quindi creare una sua rottura ?
Oppure anche se l'amplificatore passa in operate non succede nulla , ma l'importante è non trasmettere ?
Aspetto una vostra risposta

4769. Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-12 14:20:39 UTC
From: Bob
Topic: 4769 Message: 4769

New member alert! Greetings, all, from a likely soon-to-be
Alpha convert.

I put a deposit on an Alpha 9500 and should get notice
soon the amp is ready. I also have an Alpha 87A which
has developed high grid current recently. When I ask
RF Concepts about how to troubleshoot it, they say "Have
you looked at the schematics?" No, I'm not kidding.

Sorry, but schmatics are worthless without some documentation
on test points, acceptable voltages/currents, etc. After
getting nowhere with them on e-mails over the last two weeks,
I am a hair's breadth from (1) throwing my Alpha 87A into
the Hudson River (after removing the transformer so I don't
warp the chassis during transport), (2) calling RF Concepts
and getting a refund on my Alpha 9500 deposit, and (3)
ordering an Acom 2000A.

It is an artifact of ham radio that while transceiver
technology advancements cause radios to be obsoleted every
few years, amplifier technology has been pretty stable over
the last 40 years. The venerable Heath SB-220 is not too
conceptually different from many offered today, outside of
internal computer control. My point is, companies should
offer superior support on legacy amplifiers, because people
simply hold onto them longer! My Alpha 87A is the immediate
predecessor to the 9500, but getting support on it is
proving to be more painful than it is worth. If they simply
offered a service manual, I could at least have a chance
of fixing it before I die of old age waiting for them to
reply to my e-mails with their useless drivel...

The more research I do, the more I am becoming convinced
that going with the Acom 2000A would be one of the wisest
things I can do with my hard-earned beans.

Any experiences and advice from the membership would be
greatly appreciated.

Thanks in advance and 73,

Bob WA4FOM

Rumor has it the Alpha 9500 mailing list is full of unhappy people.
This list tends to be quiet as there is very little to complain about.

From: bmarton
Topic: 4769 Message: 4771

Bob,

For what it might be worth in terms of making your decision, I pass on this to you:

My Acom 2000A developed a problem with one of the tubes suddenly running much hotter than the other. I called Krassy on his cell phone

to discuss the problem and the conclusion was that one of the tubes was failing. Krassy drove up to my house on that following weekend

with a box of spare new tubes and we installed one after another until the parameters matched perfectly in the amp and the temperature differential

was within 1 or 2 degrees between tubes. He then ran through a complete alignment and the Acom has been up and running perfectly ever since.

Krassy and I got on the air and worked a group of stations then had dinner with a great time hanging out for the evening. May I ask what company

you know of in which the CEO drives an hour and an half to see your station and repair your amp for you?

I am totally sold on Acom and the product is the best on the market with great customer service. And what other company gives you the CEO's

cell phone number to have? The total cost of repair with new tubes; dinner.

Bruce K1XR

Thanks much! One or two more testimonials like that
and I'm ordering the Acom!

I purchased my amp from the Medford, MA Acom sales office, which at the time was the only sales branch in the US.

Krassy and Will run this company. I know very little of the Array Solutions sales department, however I have had some dealings with them on other products and they too were very good.

Will is no longer working with Krassy and Krassy is winding down his business with Acom.

Array Solutions has been working with Acom Bulgaria and Krassy to transition sales and support for about 3 years. We have all amplifiers in stock.

73,

Bob W5OV
Array Solutions

From: bmarton
Topic: 4769 Message: 4776

I did not know this and I am sad to hear that they are getting out of the business as Krassy is very good at Acom.

However I am sure that Array Solutions will prove to be just as good to deal with; the only difference being I won't be able to simply drive over with the amp in the event of troubles.

Will is no longer working with Krassy and Krassy is winding down his business with Acom.

Array Solutions has been working with Acom Bulgaria and Krassy to transition sales and support for about 3 years. We have all amplifiers in stock.

4777. Dumping Alpha 87A for Acom 2000A

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-12 17:38:05 UTC
From: W1JCW
Topic: 4769 Message: 4777

One of the best decisions you will ever make !!

I had a similar issue with Alpha and Molly. The two engineers I spoke with were okay to work with
and went of their way to help me. Then I was told by Molly that if I needed further phone support
I would have to pay for it !! BS I told her. She then offered an RMA option and I sent the controller
board into them. That turned out to be the old bait and switch in that Molly tells me that they cannot
fix it for the price she quoted ! Of course we had a long conversation about this.
I told her what I thought and that she just lost a 9500 customer over deceptive practices too !

I shopped for the Acom 2000a and found a gem. I'm extremely happy with the performance and very impressed with the customer service which you don't need because they amp does not have
the quirky things wrong with it that Alpha products do.

By the Acom and you will love yourself for it there is one for sale on qth.com at this time.

Subject: [acom-list] Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

New member alert! Greetings, all, from a likely soon-to-be
Alpha convert.

I put a deposit on an Alpha 9500 and should get notice
soon the amp is ready. I also have an Alpha 87A which
has developed high grid current recently. When I ask
RF Concepts about how to troubleshoot it, they say "Have
you looked at the schematics?" No, I'm not kidding.

Sorry, but schmatics are worthless without some documentation
on test points, acceptable voltages/currents, etc. After
getting nowhere with them on e-mails over the last two weeks,
I am a hair's breadth from (1) throwing my Alpha 87A into
the Hudson River (after removing the transformer so I don't
warp the chassis during transport), (2) calling RF Concepts

and getting a refund on my Alpha 9500 deposit, and (3) ordering an Acom 2000A.

It is an artifact of ham radio that while transceiver technology advancements cause radios to be obsoleted every few years, amplifier technology has been pretty stable over the last 40 years. The venerable Heath SB-220 is not too conceptually different from many offered today, outside of internal computer control. My point is, companies should offer superior support on legacy amplifiers, because people simply hold onto them longer! My Alpha 87A is the immediate predecessor to the 9500, but getting support on it is proving to be more painful than it is worth. If they simply offered a service manual, I could at least have a chance of fixing it before I die of old age waiting for them to reply to my e-mails with their useless drivel...

The more research I do, the more I am becoming convinced that going with the Acom 2000A would be one of the wisest things I can do with my hard-earned beans.

Any experiences and advice from the membership would be greatly appreciated.

Thanks in advance and 73,

Bob WA4FOM

Bob,

If there is a way of getting your deposit back - then go for an ACOM 2000. You will have this amplifier long after everything else in your shack has been replaced.

Of course, you are asking the wrong people here becasue we are already converts but the testimonials from here - even after the brown stuff has hit the fan (and it does sometimes) is amazing. I do not know of one person with any ACOM products that are fundamentally unhappy with either the product - or the service (whether that be locally delivered or straight from the factory).

.. but the product itself is atterly awe-inspiring! :)

Callum.

Hi Bob,
I have had an both the 87A and now an Acom 2KA. Both work well and no complaints about the Alpha. I have not see any problems with either amp. I have been on this reflector since before I purchase my Acom from the guys in New England about 4 years ago. Any time some one mentions a problem I have seen nothing but helpful advice and even suggestions of contacting the factory in Bulgaria. Since Array Solutions has been selling the amp they have also jumped in with helpful advice. The community involved with the Acom are supportive and helpful. I believe the Acom is still cheaper than the Alpha so to me it's a no brainer.

4780. Re: [acom-list] Dumping Alpha 87A for Acom 2000A

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-12 18:02:26 UTC
From: Hans Remeeus
Topic: 4769 Message: 4780

Hello,

For about half a year or so I had the Alpha 87A side-by-side with the Acom 2000A. Very good to compare!

I noticed a hughe difference in output power of the Alpha 87A, with exactly the same input power from the exciter. E.g. 1kW on most of the bands and 2.2kW on 24 MHz. This could bring me in big problems with my antenna tuner and other devices. And of course with my license ;-)

After a few months the Alpha 87A stopped working on 40 Meters. When I sent questions to Alpha I had to wait for at least one week and still get a very moderate answer. I sent three messages and got one answer which did'nt gave me a solution for my problem. After two more messages and one week waiting still no reply! Glenn was okay, but when Glenn was not available there was nobody else who could help with good technical advise. This is a real horror story when you buy a linear amplifier of $7.000!

We did some investigations on our own and saw that a part of the bandswitch was burned. Note that the Alpha 87A is an automatic linear and I did'nt switch anything while transmitting.
It was a lot of work to fix the problem with the bandswitch.

I sold the 87A.

When you send e-mail to Acom you will get a full reply, sometimes with photos, drawings and diagrams, the same day or the day after. Stan LZ1IU is PERFECT!!

The only thing I really liked of the 87A was the look. I like black coloured sets. When I would be a designer of Acom I had made it all black, instead of the dull colour they have now.

73!

From: stephen.tripp@snet.net
Topic: 4769 Message: 4781

I just came from the Florida Hamfest and Alpha was there. I mentioned the issue about getting a detailed schematic and service for the 87a amp. He claimed the will service any amp and will provide the same schematic their techs use. Of course this is a sales rep claiming this so one must consider the source.
I have had my 2000a since 2001 (does that make it a 2001a) and had 2 tbls with it that Will and Krassy took care of for free snd it was one of their demo smps. Great amp and company.

4782. Acom 2000A mounted vertically??

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-12 19:14:15 UTC
From: nu6x
Topic: 4782 Message: 4782

Due to space considerations, I want to put the 2000A RF deck under my desk setup vertically with the right side (transformer side) down. The tube specs say the tube can be mounted in any position. Acom test the 2000A in that position but seem to be a little nervous about long term usage in that position though they have not seen any failures due to this.

Is anybody running their amp in this position???

Thanks....Mark NU6X Sedona, AZ

From: KR5DX
Topic: 4782 Message: 4783

This does not sound like a good idea to me.
The amp is designed to stand flat on its feet.
I foresee heat issues and also stress on the chassis with the 50lbs transformer "hanging" from the chassis.
Perhaps a call to Array Solutions would give you the right answer.

From: Dick Flanagan
Topic: 4782 Message: 4784

Hi, Mark.

I think that would be a very bad idea. In time gravity could warp the tuning capacitors and the thought of that 50lb transformer just hanging by its four bolts--and the stress that would put on the chassis--would keep me awake at night.

As the Operator's Manual states "...take care not to torque or twist the chassis nor let the amplifier stand on edge."

Dick

I did contact Array Solutions and Jay rapidly passed it on to Acom with the following reply:

"According to the tube producer specs, the GU74B can operate in any position (it has been in use on Russian airplanes). In fact we turn the amplifiers the way Mark is asking for but for several hours during tunings or repair and have had no problems. Anyway, I would prefer the normal position for prolonged periods.
**
**
**
*73 Stan LZ1IU"
*
I would also prefer to keep it horizontal but that would require other compromises that I don't want to have to make. I am mostly worried about the tube grids sagging and then shorting. I know a while back I heard of someone operating in that position. I'm trying to determine if anyone has been successful or unsuccessful in this prolonged operating position.

Thanks and 73.....Mark NU6X

John,

Sorry, I can't let you bad mouth Molly. Hams are the cheapest worms on the planet. Have you ever tried to get "free" Tech support for your 10 year old software? Call Dell and want FREE tech support for your 10 year old Dell computer? Did you ever call an auto mechanic, describe your issue over the phone and expect your repair to equal the estimate without the mechanic seeing the car? Shame on Molly for trying to help you over the phone and making the stupid mistake of giving you an ESTIMTE over the phone. She is straight forward one of the most honest people I have ever dealt with. I have owned 3 2000A's. No complaints about Acom or Alpha. I currently have an Alpha 9500.

Do you complain about the ATM fee? Does your Dr answer the phone, spend 20minutes on the phone with you for free? WOW.....hams are cheap!!

Molly is indeed a nice person, and my intent wasn't to "mean-mouth" anyone. I think, though, I should get something better than "have you looked at the schematics?" over a two week period. Something like "try measuring at thus-and-such test point and let me know what you get" would have been something. I realize the 87A is considered obsolete, and I was not expecting instant miracles; I just expected something constructive, or maybe a link where I could download something that could be called a Service Manual so I could take a crack at it myself and not have to bug them constantly. Apparently this is classified information, assuming it exists...

Guys, I'm not going down this path. Sooner or later this will deteriorate into a discussion of how the "no-code license" has compromised ham radio.

I had a bad experience. I e-mailed for free assistance. I got nothing constructive for two weeks. If someone had said "give us a credit card number" I would have given them the number. Apparently they don't have the time or personnel to ask for my money.

If I were cheap, I wouldn't have bought an Alpha in the first place. I'm just amazed at the lack of (1) constructive advice from them and (2) real service documentation for a product they no longer sell.

This is making my decision to get the Acom all the easier.

There is no problem running a 2000A on its side I know two people who have done it for years, transformer end down. The tubes don't care, and air flow is all "forced", not radiated or conducted. Its just not a problem.

This does not sound like a good idea to me.
The amp is designed to stand flat on its feet.
I foresee heat issues and also stress on the chassis with the 50lbs transformer "hanging" from the chassis.
Perhaps a call to Array Solutions would give you the right answer.

Paul -

I can bad mouth anyone I wish as it's part of the constitution. I know Molly, like her and still speak with her today.
I don't accept or tolerate being quoted one price and expect certain terms to have them changed once my parts are received or service
is to be delivered. I'm not complaining, I'm stating facts and this is why I don't own an alpha but own the Acom 2000a.

Your questions are all answered with a "no".

There is no shame on Molly indicated from me. For my case she was not a person of her word. If I provide a price for services and I made a mistake then guess what I eat it !

Yes hams are cheap I certainly know and understand this, so are many others that are not hams.

I'm a person of my word and I stick to it.

If I make a mistake I admit it and make it right regardless of the cost to myself .
I learn from my mistakes and don't make them it again.

Bob,

I've owned an 87A for nearly 17 years and a 2000A for about 12 years. In my book, both amps are terrific: great design, great build quality.

Each amp has had its share of problems over the years, but this is s
something you would expect from devices of this nature. I've been lucky: I've never had to ship either amp for repair. I've been able to fix nearly all the problems myself, with some study of the schematics and help from the factory.

In three cases (once with the 87A and twice with the 2000A), the amps required service I couldn't perform, but I was able to drive the amp an hour or two to get service. In the case of the 87A, I was just lucky that their best tech was visiting our region. With the 2000A, I was just lucky that Krassy operates out of our region.

All in all, I've had to put very little money into the amps -- a darned sight less than car maintenance would have cost!

That brings me to customer support. There's no service manual for either amp, and the usefulness of the schematics is about the same -- sometimes helpful, sometimes not, and very few test point voltages. There have been numerous times when I've needed help from the factory, and I've always gotten it. But the experiences with the two companies has been quite different.

Service from RF Concepts depends on the problem. There are many problems they can diagnose quickly from the fault codes. I've seen Glenn from RF Concepts respond quickly with useful help about such problems on the Alpha87A reflector many times. The same has been true when I've emailed him or gotten him on the phone. He has a set of documents that describe troubleshooting for many of the fault codes and will email them to you.

That said, RF Concept's Brad is the world's expert on the 87A. He knows absolutely everything about that amp and has seen every problem under the sun. If you can get him on the phone for one minute you'll probably get the answer you need. One time I was going back and forth with Glenn on problems I was having with fault codes related to the TX PIN diodes, and Brad overheard Glenn's end of the conversation. Brad said, "Tell him to check L1 on the T/R board. The insulation has probably worn away". Sure enough, the insulation was gone and the inductor had arced and punched a hole in the PCB. The trouble is, Brad's their best tech and he's very, very busy.

This problem occurred last year, probably before they instituted the paid service call policy (I didn't have to pay for the call.) But I understand that time is money, my amp is *way*, *way* out of warranty, and Alpha should be paid for helping me. I'm perfectly willing to pay for phone service, provided it's reasonably efficient and effective. I agree that RF Concepts has a tendency to throw up their hands and say, "Send us the amp." It's probably cheaper for them in the long run. But its not always best for the customer.

Service from Acom has been excellent. Early on, Krassy took care of me, but I quickly learned that the folks at the factory in Bulgaria were very happy to help via email. In fact, the president of the company helped me back in the early 2000's when I first got the 2000A. Since then, Stan has been fantastic about answering all my questions, helping me to troubleshoot problems, and sending me detailed information about repairs and adjustments, often photo-illustrated! Fairly recently, he sent me some brand-new, relatively expensive parts to fix a problem that had nagged me since I bought the amp. Stan said that since the amp showed the problem when it was under warranty, they would replace the parts at no charge. All I had to do was pay postage.

I haven't dealt with Array Solutions on service yet, but I've always been happy with their service when I've bought other products from them, and I'm sure they do a good job on the 2000A.

The bottom line is that good service can be obtained for either amp. I would give the 2000A the advantage because 1) they don't charge for phone/email service, and 2) it's not an obsolete product. The latter is my biggest concern about the 87A: it's officially obsolete and some of the parts are no longer available from any source other than RF Concepts. When their stock runs out, it may not be possible to repair the amp without redesigning certain circuits (and maybe having to fool the fault sensors.)

Although my 87A is working well (knock on wood) and I feel confident that I can fix many problems with it, I've certainly been thinking about replacing it. But that gets into how I use my two amps:

The 87A is the primary amp in my SO2R contest station. I do 95% of my running on the 87A, and just use the 2000A for S&P. Consequently, the 87A gets a lot more use than the 2000A. There are two reasons I use the 87A for running. First, the PIN diodes are silent, and I used to have both amps in my shack. Now they're remote in the basement, so this reason is less important. However, vacuum relays do have a maximum number of cycles, and 6-8 contests per year will run up the cycles quickly, especially when QSK is used. The second reason I use the 87A is AlphaMax. I love the 87A's ability to tune on the fly. The 2000A has to be pre-programmed for every segment and every antenna. Luckily, I've written software to automatically select the antennas and segments on the 2000A, so this, too, is less of an issue than it used to be.

So what to do? Ideally, I would replace the 87A with a solid state amp, but no one is making a reliable 1500W solid state amp at an affordable price. I have no interest in the RF Concepts 9500: it has a lot of features I don't need and it's $1000 more than a new 2000A. And, like some of you, I've heard that some 9500 owners are not happy with the amp. That leaves only one choice: the 2000A. I should probably sell my 87A now, while I can still get good money for it, and buy a 2000A. But knowing me, I won't do it until the 87A reaches the end of its repairable lifetime. I just love the amp too much.

Bob,

I've owned an 87A for nearly 17 years and a 2000A for about 12 years. In my book, both amps are terrific: great design, great build quality.

Each amp has had its share of problems over the years, but this is s
something you would expect from devices of this nature. I've been lucky: I've never had to ship either amp for repair. I've been able to fix nearly all the problems myself, with some study of the schematics and help from the factory.

In three cases (once with the 87A and twice with the 2000A), the amps required service I couldn't perform, but I was able to drive the amp an hour or two to get service. In the case of the 87A, I was just lucky that their best tech was visiting our region. With the 2000A, I was just lucky that Krassy operates out of our region.

All in all, I've had to put very little money into the amps -- a darned sight less than car maintenance would have cost!

That brings me to customer support. There's no service manual for either amp, and the usefulness of the schematics is about the same -- sometimes helpful, sometimes not, and very few test point voltages. There have been numerous times when I've needed help from the factory, and I've always gotten it. But the experiences with the two companies has been quite different.

Service from RF Concepts depends on the problem. There are many problems they can diagnose quickly from the fault codes. I've seen Glenn from RF Concepts respond quickly with useful help about such problems on the Alpha87A reflector many times. The same has been true when I've emailed him or gotten him on the phone. He has a set of documents that describe troubleshooting for many of the fault codes and will email them to you.

That said, RF Concept's Brad is the world's expert on the 87A. He knows absolutely everything about that amp and has seen every problem under the sun. If you can get him on the phone for one minute you'll probably get the answer you need. One time I was going back and forth with Glenn on problems I was having with fault codes related to the TX PIN diodes, and Brad overheard Glenn's end of the conversation. Brad said, "Tell him to check L1 on the T/R board. The insulation has probably worn away". Sure enough, the insulation was gone and the inductor had arced and punched a hole in the PCB. The trouble is, Brad's

their best tech and he's very, very busy.

This problem occurred last year, probably before they instituted the paid service call policy (I didn't have to pay for the call.) But I understand that time is money, my amp is *way*, *way* out of warranty, and Alpha should be paid for helping me. I'm perfectly willing to pay for phone service, provided it's reasonably efficient and effective. I agree that RF Concepts has a tendency to throw up their hands and say, "Send us the amp." It's probably cheaper for them in the long run. But its not always best for the customer.

Service from Acom has been excellent. Early on, Krassy took care of me, but I quickly learned that the folks at the factory in Bulgaria were very happy to help via email. In fact, the president of the company helped me back in the early 2000's when I first got the 2000A. Since then, Stan has been fantastic about answering all my questions, helping me to troubleshoot problems, and sending me detailed information about repairs and adjustments, often photo-illustrated! Fairly recently, he sent me some brand-new, relatively expensive parts to fix a problem that had nagged me since I bought the amp. Stan said that since the amp showed the problem when it was under warranty, they would replace the parts at no charge. All I had to do was pay postage.

I haven't dealt with Array Solutions on service yet, but I've always been happy with their service when I've bought other products from them, and I'm sure they do a good job on the 2000A.

The bottom line is that good service can be obtained for either amp. I would give the 2000A the advantage because 1) they don't charge for phone/email service, and 2) it's not an obsolete product. The latter is my biggest concern about the 87A: it's officially obsolete and some of the parts are no longer available from any source other than RF Concepts. When their stock runs out, it may not be possible to repair the amp without redesigning certain circuits (and maybe having to fool the fault sensors.)

Although my 87A is working well (knock on wood) and I feel confident that I can fix many problems with it, I've certainly been thinking about replacing it. But that gets into how I use my two amps:

The 87A is the primary amp in my SO2R contest station. I do 95% of my running on the 87A, and just use the 2000A for S&P. Consequently, the 87A gets a lot more use than the 2000A. There are two reasons I use the 87A for running. First, the PIN diodes are silent, and I used to have both amps in my shack. Now they're remote in the basement, so this reason is less important. However, vacuum relays do have a maximum number of cycles, and 6-8 contests per year will run up the cycles quickly, especially when QSK is used. The second reason I use the 87A is AlphaMax. I love the 87A's ability to tune on the fly. The 2000A has to be pre-programmed for every segment and every antenna. Luckily, I've written software to automatically select the antennas and segments on the 2000A, so this, too, is less of an issue than it used to be.

So what to do? Ideally, I would replace the 87A with a solid state amp, but no one is making a reliable 1500W solid state amp at an affordable price. I have no interest in the RF Concepts 9500: it has a lot of features I don't need and it's $1000 more than a new 2000A. And, like some of you, I've heard that some 9500 owners are not happy with the amp. That leaves only one choice: the 2000A. I should probably sell my 87A now, while I can still get good money for it, and buy a 2000A. But knowing me, I won't do it until the 87A reaches the end of its repairable lifetime. I just love the amp too much.

If you're referring to the Acom Technical CD, that only contains the operating manual, the schematics, and the old AcomTools program (which doesn't work on modern PCs.) If there's a real service manual available, I've never seen it. Has anyone else.

4798. Re: Dumping Alpha 87A for Acom 2000A

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-13 17:19:38 UTC
From: Andrey
Topic: 4769 Message: 4798

For what is worth - when I got my ACOM 1000 (bought it used from a fellow ham, the amp was about 6 years old), I emailed ACOM Bulgaria with a couple of questions. I had no issues with the amp, just wanted to know what was the procedure for tube replacement. Next day, I received an email from Stan with a zip file attachment. The ZIP included everything - the whole service documentation, schematics, alingment procedures, picures of key components involving tube repacement etc. Pretty much everything that I might need to repair the amp by myself should I ever have to. He answerd all my questions in a great detail and was extremly helpful! He even offered a tour of the factory should I ever visit Bulgaria.
I noticed that I had an older firmware version and asked Stan about it - he offered to send me the BIN file so I can program my own EPROM right away or If I wanted I could have an EPROM chip already programmed with the latest firmware version. I asked for the chip and got one for free. He even went to the records and gave me information about my particular amp - when was manufactured, what was the original serial number and date code of the tube, alignment data, etc.

Here is another example of ACOM's dedication - when I bought the amp, there were some scratches on the side of the cover. I called Krassy on his cell (he has given me the number when we met the year before at Dayton) and asked to buy a replacement cover. His answer was: "I currently dont have any in stock. I am waiting for shipment from ACOM Bulgaria but we are going to get them in a few weeks. If you need to get it fixed really fast - just send me the old cover and I will arrange to have it stripped and powder coated and I promiss you it will look exactly as a new one! Oh, and btw d I'll do it for free, dont worry about it"

Now, that's a service, going out of his way to fix a few artificial scratches on a cover.

Hope this helps!

4799. Re: Trading 87a for Acom 2000a

From: Kenneth
Topic: 4799 Message: 4799

I feel compelled to get in on this since I have had experience with both.

I have had a long line of Alpha amps, dating back to the ETO days.
My difficulties with Alpha started when I had a repair of the AC board on my 87a that cost me over $1600. A diode went out, they replaced the board. No wholesale replacement of caps, nada.
That put me on notice with them.

Later it was a problem getting a replacement fan for the bird cage.
It took over 6 months with a new story each time about having them soon, but no calls. No responses to emails. All of this was before
the company was sold.

I finally replaced the fan and sold the 87a. At that point I already had an ACOM 2000a and knew how solid the service was. I now have two Acom 2000a amps, and they have both had repairs. My eyes no longer allow me to dig into them, so repairs were done in Massachusetts, where I purchased them. I don't think I have paid a penny for these repairs, only the shipping one direction. Kassy and his staff have been great and I hate to see them leave the business. I have had no dealings with Array Solutions re Acom, but I only hope they are half as good.

Everything will eventually need repair. It is then that you really measure the value of who you are dealing with.

I now own an Acom 2000A that is a delight! It is simply a thing of ham radio beauty. I believe that replacing my three failed Alpha 9500's with this amplifier is one of the best decisions I have ever made in my ham radio "career". In the end Alpha/RF Concepts refunded all of my money and for this they get good marks but I'll never purchase another product from them Three strikes, well you know how it goes .. For what it is worth all three amps had different issues! At least they were not repeating the same mistakes! My Acom has only been here since late September but it has already been shown to be far more reliable than the best of the three Alpha 9500's that graced my shack. It just plain works! No more fault codes, no more black smoke nothing but quiet reliable power!

As to Molly, she is a delightful person that is always wonderful to talk to on the phone but in my experience she was challenged to act on the things she promised. I had countless numbers of instances of the amplifier failing where she would promise to send replacement parts and she would forget. Dealing with her lack of follow through was frustrating at best and at times it made me livid!
I know of a number of people who have Alpha 9500's and are doing well with them but if you want to "play the odds" buy the Acom. You'll be happy you did! I purchased my Acom from Array Solutions as they have a track record with me but I am sure you cannot go wrong working with Krassy. Both are a good bet....

Subject: [acom-list] Re: Dumping Alpha 87A for Acom 2000A

For what is worth - when I got my ACOM 1000 (bought it used from a fellow ham, the amp was about 6 years old), I emailed ACOM Bulgaria with a couple of questions. I had no issues with the amp, just wanted to know what was the procedure for tube replacement. Next day, I received an email from Stan with a zip file attachment. The ZIP included everything - the whole service documentation, schematics, alingment procedures, picures of key components involving tube repacement etc. Pretty much everything that I might need to repair the amp by myself should I ever have to. He answerd all my questions in a great detail and was extremly helpful! He even offered a tour of the factory should I ever visit Bulgaria.
I noticed that I had an older firmware version and asked Stan about it - he offered to send me the BIN file so I can program my own EPROM right away or If I wanted I could have an EPROM chip already programmed with the latest firmware version. I asked for the chip and got one for free. He even went to the records and gave me information about my particular amp - when was manufactured, what was the original serial number and date code of the tube, alignment data, etc.

Here is another example of ACOM's dedication - when I bought the amp, there were some scratches on the side of the cover. I called Krassy on his cell (he has given me the number when we met the year before at Dayton) and asked to buy a replacement cover. His answer was: "I currently dont have any in stock. I am waiting for shipment from ACOM Bulgaria but we are going to get them in a few weeks. If you need to get it fixed really fast - just send me the old cover and I will arrange to have it stripped and powder coated and I promiss you it will look exactly as a new one! Oh, and btw d I'll do it for free, dont worry about it"

Now, that's a service, going out of his way to fix a few artificial scratches on a cover.

Hope this helps!

> I've owned an 87A for nearly 17 years and a 2000A for about 12 years. In my book, both amps are terrific: great design, great build quality.
>
> Each amp has had its share of problems over the years, but this is s
> something you would expect from devices of this nature. I've been lucky: I've never had to ship either amp for repair. I've been able to fix nearly all the problems myself, with some study of the schematics and help from the factory.
>
> In three cases (once with the 87A and twice with the 2000A), the amps required service I couldn't perform, but I was able to drive the amp an hour or two to get service. In the case of the 87A, I was just lucky that their best tech was visiting our region. With the 2000A, I was just lucky that Krassy operates out of our region.
>
> All in all, I've had to put very little money into the amps -- a darned sight less than car maintenance would have cost!
>
> That brings me to customer support. There's no service manual for either amp, and the usefulness of the schematics is about the same -- sometimes helpful, sometimes not, and very few test point voltages. There have been numerous times when I've needed help from the factory, and I've always gotten it. But the experiences with the two companies has been quite different.
>
> Service from RF Concepts depends on the problem. There are many problems they can diagnose quickly from the fault codes. I've seen Glenn from RF Concepts respond quickly with useful help about such problems on the Alpha87A reflector many times. The same has been true when I've emailed him or gotten him on the phone. He has a set of documents that describe troubleshooting for many of the fault codes and will email them to you.
>
> That said, RF Concept's Brad is the world's expert on the 87A. He knows absolutely everything about that amp and has seen every problem under the sun. If you can get him on the phone for one minute you'll probably get the answer you need. One time I was going back and forth with Glenn on problems I was having with fault codes related to the TX PIN diodes, and Brad overheard Glenn's end of the conversation. Brad said, "Tell him to check L1 on the T/R board. The insulation has probably worn away". Sure enough, the insulation was gone and the inductor had arced and punched a hole in the PCB. The trouble is, Brad's their best tech and he's very, very busy.
>
> This problem occurred last year, probably before they instituted the paid service call

policy (I didn't have to pay for the call.) But I understand that time is money, my amp is *way*, *way* out of warranty, and Alpha should be paid for helping me. I'm perfectly willing to pay for phone service, provided it's reasonably efficient and effective. I agree that RF Concepts has a tendency to throw up their hands and say, "Send us the amp." It's probably cheaper for them in the long run. But its not always best for the customer.
>
> Service from Acom has been excellent. Early on, Krassy took care of me, but I quickly learned that the folks at the factory in Bulgaria were very happy to help via email. In fact, the president of the company helped me back in the early 2000's when I first got the 2000A. Since then, Stan has been fantastic about answering all my questions, helping me to troubleshoot problems, and sending me detailed information about repairs and adjustments, often photo-illustrated! Fairly recently, he sent me some brand-new, relatively expensive parts to fix a problem that had nagged me since I bought the amp. Stan said that since the amp showed the problem when it was under warranty, they would replace the parts at no charge. All I had to do was pay postage.
>
> I haven't dealt with Array Solutions on service yet, but I've always been happy with their service when I've bought other products from them, and I'm sure they do a good job on the 2000A.
>
> The bottom line is that good service can be obtained for either amp. I would give the 2000A the advantage because 1) they don't charge for phone/email service, and 2) it's not an obsolete product. The latter is my biggest concern about the 87A: it's officially obsolete and some of the parts are no longer available from any source other than RF Concepts. When their stock runs out, it may not be possible to repair the amp without redesigning certain circuits (and maybe having to fool the fault sensors.)
>
> Although my 87A is working well (knock on wood) and I feel confident that I can fix many problems with it, I've certainly been thinking about replacing it. But that gets into how I use my two amps:
>
> The 87A is the primary amp in my SO2R contest station. I do 95% of my running on the 87A, and just use the 2000A for S&P. Consequently, the 87A gets a lot more use than the 2000A. There are two reasons I use the 87A for running. First, the PIN diodes are silent, and I used to have both amps in my shack. Now they're remote in the basement, so this reason is less important. However, vacuum relays do have a maximum number of cycles, and 6-8 contests per year will run up the cycles quickly, especially when QSK is used. The second reason I use the 87A is AlphaMax. I love the 87A's ability to tune on the fly. The 2000A has to be pre-programmed for every segment and every antenna. Luckily, I've written software to automatically select the antennas and segments on the 2000A, so this, too, is less of an issue than it used to be.
>
> So what to do? Ideally, I would replace the 87A with a solid state amp, but no one is making a reliable 1500W solid state amp at an affordable price. I have no interest in the RF Concepts 9500: it has a lot of features I don't need and it's $1000 more than a new 2000A. And, like some of you, I've heard that some 9500 owners are not happy with the amp. That leaves only one choice: the 2000A. I should probably sell my 87A now, while I can still get good money for it, and buy a 2000A. But knowing me, I won't do it until the 87A reaches the end of its repairable lifetime. I just love the amp too much.

Bob,

To start, I do not think you can go wrong choosing ACOM. I bought my 2000A used two years ago and
have been mostly happy. It is not perfect but it is pretty good.

The Pros:

It IS a well built, legal limit auto tune amplifier that works very well. I am highly pleased with mine
and if someone offered to trade me an Alpha 9500 for it I would do it. Then I would sell the Alpha,
buy another ACOM and use the rest of the money to buy something else nice.

The Cons:

1. Do not expect either Acom America or Array Solutions to be of much help. When I have had issues I ended up emailing Acom Bulgaria... They are very helpful but it takes a day for each
iteration.

2. The serial interface is buggy and poorly documented. There are some quirks that will have you
scratching your head if you run into them. This may or may not be an issue depending on how much
you plan to automate station. My understanding from someone who has worked with both is Alpha
has their issues in this area also.

3. The arc fault detect circuit is subject to false tripping if there are any switching transients in the
transceiver and the antenna load is anything but perfectly matched and resistive. While it is not
well documented there are several ICOM, at least one TenTec and the Flex 5k with certain software
flavors. In the case of the ICOMs there is a high pass filter design floating around to handle it, in the
case of the TenTec and the Flex, there are software versions that fix it.

Hope this is of some help.

Bill,

While you're correct that on very difficult problems, or especially on circumstances that we may not have seen before, consulting with Acom in Bulgaria may be necessary. It definitely streamlines the process by leveraging their much more extensive and varied experience.

Even so, I'd like to think we're marginally helpful to our customers from time to time.

4804. RE: [acom-list] Re: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-14 02:10:48 UTC
From: Howard K2HK
Topic: 4769 Message: 4804

Bill,
I have owned my Acom since 1999 and have had a different experience, especially with one and three.
The Cons:
1. Do not expect either Acom America or Array Solutions to be of much help. When I have had issues I ended up emailing Acom Bulgaria... They are very helpful but it takes a day for each
iteration.
I have had excellent experiences with all three sources although I believe only Array Solutions and Acom Bulgaria are the current choices. There have been enough examples so I won't go into mine but in every instance and they were very few the response was outstanding.
2. The serial interface is buggy and poorly documented. There are some quirks that will have you
scratching your head if you run into them. This may or may not be an issue depending on how much
you plan to automate station. My understanding from someone who has worked with both is Alpha
has their issues in this area also.
No argument here. It was never a high point and not touted by the company when the amp was introduced.

3. The arc fault detect circuit is subject to false tripping if there are any switching transients in the
transceiver and the antenna load is anything but perfectly matched and resistive. While it is not
well documented there are several ICOM, at least one TenTec and the Flex 5k with certain software
flavors. In the case of the ICOMs there is a high pass filter design floating around to handle it, in the
case of the TenTec and the Flex, there are software versions that fix it.

This is where I strongly disagree. The arc default has never been buggy just sensitive to problems within the output path. It has limited many problems that might be difficult to find until the damage has been done. Poor connections, high resistance shorts, poor coax and the more obvious problems will certainly shut down the system. When I first put my amp inline in 1999 I thought the same way you did until I eventually learned the amp responded like no other I knew at that time. I eventually learned all the arc faults were exactly that. I guess you might say it is also a high priced system check. By the way I am using the original tubes with the same output that they had 13 years ago.

Subject: Re: [acom-list] Re: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

Bob,

To start, I do not think you can go wrong choosing ACOM. I bought my 2000A used two years ago and

have been mostly happy. It is not perfect but it is pretty good.

The Pros:

It IS a well built, legal limit auto tune amplifier that works very well. I am highly pleased with mine

and if someone offered to trade me an Alpha 9500 for it I would do it. Then I would sell the Alpha,

buy another ACOM and use the rest of the money to buy something else nice.

The Cons:

1. Do not expect either Acom America or Array Solutions to be of much help. When I have had issues I ended up emailing Acom Bulgaria... They are very helpful but it takes a day for each
iteration.

2. The serial interface is buggy and poorly documented. There are some quirks that will have you

scratching your head if you run into them. This may or may not be an issue depending on how much

you plan to automate station. My understanding from someone who has worked with both is Alpha

has their issues in this area also.

3. The arc fault detect circuit is subject to false tripping if there are any switching transients in the

transceiver and the antenna load is anything but perfectly matched and resistive. While it is not

well documented there are several ICOM, at least one TenTec and the Flex 5k with certain software

flavors. In the case of the ICOMs there is a high pass filter design floating around to handle it, in the

case of the TenTec and the Flex, there are software versions that fix it.

Hope this is of some help.

From: Bill Ockert - ND0B
Topic: 4769 Message: 4805

Bob,

I have not intent of getting into a peeing match with you on this and will say up front I have several
Array Solutions products and have been very happy with both the products and the support.

However support on the Acom is a bit different story in that myself in the case of Arrary Solutions and
myself and a few others in the case of Acom America brought up the arc fault issue and did not get an
answer in either case. It turned out this was a known issue and that the answer could be had as
easily emailing the Acom factory. Once I finally did that I had the schematic for a simple filter that would
take care of the problem in less than a day.

I would suggest that Array Solutions and / or Acom America could have emailed the factory, told them about
the flakes they were talking to on the phone and found out that we were dealing with a known issue. Thus
my suggestion that if support is needed it might not be as close as it would seem at first glance.

My apologies if you take offense to that suggestion but based on my personal experience it is legitimate.

Bill,

While you're correct that on very difficult problems, or especially on
circumstances that we may not have seen before, consulting with Acom in
Bulgaria may be necessary. It definitely streamlines the process by
leveraging their much more extensive and varied experience.

Even so, I'd like to think we're marginally helpful to our customers from
time to time.

From: Bill Ockert - ND0B
Topic: 4769 Message: 4806

A simple web search will pull up instances of several radios that while working perfectly fine
with other amplifiers cause an arc fault when run with the Acom with certain antenna loadings.
Some of that dialog has even been on this reflector.

As I stated before Acom has a filter design for this. After messing with the issue for several months including calls to both Acom America and to Array Solutions I finally emailed
the factory. I had the filter design the next day, I had it built and installed with the problem gone
the day after that.

No piece of gear is perfect and it gets a lot less so if those of us who own something put on rose colored glasses and act like something we own could possibly have an issue.
Had I known about the arc fault issue or had information on it been easier to come by
I would have hand months less headaches and a much better initial ownership experience.

In spite of that I would still rate the amp near 5 out of 5 and it would be my first choice.

4807. RE: [acom-list] ACOM 2000A ARC FAULT (Was: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A)

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-14 03:56:39 UTC
From: Ron Castro
Topic: 4807 Message: 4807

The filter is not always the solution, especially when using an ACOM 2000A with an Orion II. I have two HP filters in series feeding the input, and I still get Arc Faults during RTTY contests. They will happen every transmission for an hour or so (I need to reset after every time I transmit), then it won't happen for many hours, only to start again later.

I know it's not in the antennas since I can run key down at full power for a few minutes, and the Arc Fault will only show up exactly at the end of transmission, indicating that it's picking up some hot-switching in the O II that seems to come and go, possibly related to heat or a busy CPU.

After five years of enduring the problem, I have determined to do a mod that was recommended early on: desensitizing the Arc Fault circuit by placing a 50 k Ohm resistor in parallel with R132 (100 k Ohm) on the Interface board. R132 can be seen on schematic sheet #7 in Appendix A (Page 19) of the Technical Supplement. R132 is part of a voltage divider that takes rectified, filtered RF from a low-pass filter that has a pick-up somewhere after the T/R relay.

I haven't done the mod yet, but probably will this weekend, and I will report back to the list if this fixed the problem after the next RTTY contest I enter.

Subject: Re: [acom-list] Re: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

A simple web search will pull up instances of several radios that while working perfectly fine
with other amplifiers cause an arc fault when run with the Acom with certain antenna loadings.
Some of that dialog has even been on this reflector.

As I stated before Acom has a filter design for this. After messing with the issue for several months including calls to both Acom America and to Array Solutions I finally emailed
the factory. I had the filter design the next day, I had it built and installed with the problem gone
the day after that.

No piece of gear is perfect and it gets a lot less so if those of us who own something put on rose colored glasses and act like something we own could possibly have an issue.
Had I known about the arc fault issue or had information on it been easier to come by
I would have hand months less headaches and a much better initial ownership experience.

In spite of that I would still rate the amp near 5 out of 5 and it would be my first choice.

Subject: RE: [acom-list] Re: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

Bill,
I have owned my Acom since 1999 and have had a different experience, especially with one and three.

The Cons:
1. Do not expect either Acom America or Array Solutions to be of much help. When I have had issues I ended up emailing Acom Bulgaria... They are very helpful but it takes a day for each
iteration.
I have had excellent experiences with all three sources although I believe only Array Solutions and Acom Bulgaria are the current choices. There have been enough examples so I won't go into mine but in every instance and they were very few the response was outstanding.
2. The serial interface is buggy and poorly documented. There are some quirks that will have you
scratching your head if you run into them. This may or may not be an issue depending on how much
you plan to automate station. My understanding from someone who has worked with both is Alpha
has their issues in this area also.
No argument here. It was never a high point and not touted by the company when the amp was introduced.

3. The arc fault detect circuit is subject to false tripping if there are any switching transients in the
transceiver and the antenna load is anything but perfectly matched and resistive. While it is not
well documented there are several ICOM, at least one TenTec and the Flex 5k with certain software
flavors. In the case of the ICOMs there is a high pass filter design floating around to handle it, in the
case of the TenTec and the Flex, there are software versions that fix it.

This is where I strongly disagree. The arc default has never been buggy just sensitive to problems within the output path. It has limited many problems that might be difficult to find until the damage has been done. Poor connections, high resistance shorts, poor coax and the more obvious problems will certainly shut down the system. When I first put my amp inline in 1999 I thought the same way you did until I eventually learned the amp responded like no other I knew at that time. I eventually learned all the arc faults were exactly that. I guess you might say it is also a high priced system check. By the way I am using the original tubes with the same output that they had 13 years ago.

Subject: Re: [acom-list] Re: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

Bob,

To start, I do not think you can go wrong choosing ACOM. I bought my 2000A used two years ago and

have been mostly happy. It is not perfect but it is pretty good.

The Pros:

It IS a well built, legal limit auto tune amplifier that works very well. I am highly pleased with mine

and if someone offered to trade me an Alpha 9500 for it I would do it. Then I would sell the Alpha,

buy another ACOM and use the rest of the money to buy something else nice.

The Cons:

1. Do not expect either Acom America or Array Solutions to be of much help. When I have had issues I ended up emailing Acom Bulgaria... They are very helpful but it takes a day for each
iteration.

2. The serial interface is buggy and poorly documented. There are some quirks that will have you

scratching your head if you run into them. This may or may not be an issue depending on how much

you plan to automate station. My understanding from someone who has worked with both is Alpha

has their issues in this area also.

3. The arc fault detect circuit is subject to false tripping if there are any switching transients in the

transceiver and the antenna load is anything but perfectly matched and resistive. While it is not

well documented there are several ICOM, at least one TenTec and the Flex 5k with certain software

flavors. In the case of the ICOMs there is a high pass filter design floating around to handle it, in the

case of the TenTec and the Flex, there are software versions that fix it.

Hope this is of some help.

4809. Arc Fault LP Filter (was: Seriously considering dumping Alpha 87A for Acom 2000A)

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-14 12:04:03 UTC
From: Barry N1EU
Topic: 4809 Message: 4809

Agreed - Bill can you share the circuit by uploading with a note to the
Acom Group files section at http://groups.yahoo.com/group/acom-list/files/
?

There's a file in there showing a low pass filter designed by SM6CNN for
his Orion Arc Faults but it didn't come from Acom.

Thanks & 73,
Barry N1EU

Bill,

I would like to find out more about the "issue" with the Arc Fault that you describe. When did you report this to Array Solutions?

In this context, it seems you're alleging that there is something wrong with the amplifiers' design, but I have never heard of any such problem nor of any such factory recommended "filter".

Please provide details.

In 100% of the times I have had to deal with Arc Faults reported by a 2000A amplifier, there were actual Arc Faults occurring somewhere in the antenna system - including with my own 2000A which I've owned since 1999 (also on the original tubes).

I'm not offended by the suggestion that we contact Acom for information (we do this all the time anyway - almost on a daily basis) but I'm very concerned that we may have missed something that has caused you to characterize our customer service as "Do not expect either Acom America or Array Solutions to be of much help".

What you're describing does not align with what we do.

73,

Bob W5OV
Array Solutions

Bob,

I have not intent of getting into a peeing match with you on this and will say up front I have several
Array Solutions products and have been very happy with both the products and the support.

However support on the Acom is a bit different story in that myself in the case of Arrary Solutions and
myself and a few others in the case of Acom America brought up the arc fault issue and did not get an
answer in either case. It turned out this was a known issue and that the answer could be

had as
easily emailing the Acom factory. Once I finally did that I had the schematic for a simple filter that would
take care of the problem in less than a day.

I would suggest that Array Solutions and / or Acom America could have emailed the factory, told them about
the flakes they were talking to on the phone and found out that we were dealing with a known issue. Thus
my suggestion that if support is needed it might not be as close as it would seem at first glance.

My apologies if you take offense to that suggestion but based on my personal experience it is legitimate.

Bill,

While you're correct that on very difficult problems, or especially on
circumstances that we may not have seen before, consulting with Acom in
Bulgaria may be necessary. It definitely streamlines the process by
leveraging their much more extensive and varied experience.

Even so, I'd like to think we're marginally helpful to our customers from
time to time.

There is nothing like a full power amp to show up the weaknesses in your antenna and feedline system.

Every arc fault I ever had was traced to those sources.

There was a well documented issue with the Ten-Tec Orion putting out low level, low frequency spurs that often triggered the 2000A Arc Fault detector. The problem came to light in 2004. I believe the problem was worst on 40M. Ten-Tec's fix was to provide an external low pass filter for existing Orion/Acom owners and to implement a circuit change to use a different final transistor going forward.

There is a high likelihood that this issue could still crop up as hams often change rigs and amplifiers, there are plenty of Orions in the field with the original finals, and it's still a very popular radio in dx/contesting circles (i.e., 2000A users).

OK - Barry - thanks.

I have gotten several other private emails saying essentially the same thing.

The problem is apparently something wrong with the TenTec Orion - this is not something wrong with the Acom 2000A.

It's just that the 2000A reports an Arc Fault as a result of whatever this problem with the Orion radio is.

I have asked Acom in Bulgaria to provide their official comment on this Orion problem and I will post it here if they don't post it themselves.

-Bob

Plus this issue is occurring when the radio / amp are unkeyed. This would be the least likely
time for the antenna/feedline/tuner to arc.

Barry:

You can get one free from Ten Tec if you own an Orion or Orion II. I got one a few weeks ago, but it didn't cure the problem. I'm convinced it's something in the relay timing in the Orion II that goes bad causing a very small arc, or transient in the Orion T/R relay that is amplified and picked up by the Arc Fault sensor. If you do that test I mentioned a few weeks ago, you can prove that. Lock the ACOM in transmit by shorting the keying cable, transmit with the Orion, and when you un-key the Orion, the fault will happen.

BTW, the circuit is a simple Pi low pass filter...a coil and two capacitors.

Good morning Bob,

To allay all the suggestions that this is a problem in the antenna / feedline I want to point out that this issue happens when the radio / amp are
unkeyed. If it were arcing in the antenna/feedline/tuner it should happen during the transmission, not at the end of it. The other point is that
this is hard to pin on the radio because the same radios that cause it seem to work fine with other high end amplifiers. While it is easy to blame
the radios it would also be just as easy to argue that the amplifier should have filtration built into the input to keep this type of false arc fault from
occurring and thus blame the amp.

In the case of Flex there were three of us talking with Flex about this, we actually had Gerald personally involved. Of the three of us two were
having this issue, the third had never seen it. The switching transients from the fast keying appear to be being keyed by the amplifier and
then interpreted as an arc fault. In the case of my Flex 5k it started causing the issue when Flex sped up the switching time
between a couple of software versions, I started seeing the arc faults EVERY time I would unkey from Tune or when I was operating AM.
My understanding from Flex was that they had started abruptly chopping the carrier in order to switch the relays faster. Once I contacted
Acom directly, got the filter design and tested it things got better very quickly. Based on the filter characteristics Flex was able to speculate
why they were causing the amp to arc fault and put a check box in the next version of their software allowing the user to decide between
switching speed and a shaped chop off that would not cause the are fault.

The filter design is attached. While I got it from Acom it was actually designed by an Omni 2 user prior to TenTec putting in their own software
fix.

As to when I contacted you on this it would have been somewhere between September 2010 when I started having this issue and June 2011 when I
finally emailed Acom directly. In that time period I had first spoken with Acom America then waited a couple of months for no result then spoke with
you, likely in the May 2011 time frame. I finally emailed Acom on June 5, 2011 and got the response on June 6, 2011.

All of this said, again my ONLY complaint in all of this was the lack of information. Had information on what turned out to clearly be a known issue.
It would have saved a lot of time trying to figure out what was going on. It is fixed now, it works well, filter is on the shelf just in case I add a radio to the
shack that requires it, etc.

Subject: RE: [acom-list] Re: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

Bill,

I would like to find out more about the "issue" with the Arc Fault that you describe. When did you report this to Array Solutions?

In this context, it seems you're alleging that there is something wrong with the amplifiers' design, but I have never heard of any such problem nor of any such factory recommended "filter".

Please provide details.

In 100% of the times I have had to deal with Arc Faults reported by a 2000A amplifier, there were actual Arc Faults occurring somewhere in the antenna system - including with my own 2000A which I've owned since 1999 (also on the original tubes).

I'm not offended by the suggestion that we contact Acom for information (we do this all the time anyway - almost on a daily basis) but I'm very concerned that we may have missed something that has caused you to characterize our customer service as "Do not expect either Acom America or Array Solutions to be of much help".

What you're describing does not align with what we do.

73,

Bob W5OV
Array Solutions

Subject: Re: [acom-list] Re: Requesting advice: Seriously considering dumping Alpha 87A for Acom 2000A

Bob,

I have not intent of getting into a peeing match with you on this and will say up front I have several
Array Solutions products and have been very happy with both the products and the support.

However support on the Acom is a bit different story in that myself in the case of Arrary Solutions and
myself and a few others in the case of Acom America brought up the arc fault issue and did not get an
answer in either case. It turned out this was a known issue and that the answer could be had as

easily emailing the Acom factory. Once I finally did that I had the schematic for a simple filter that would
take care of the problem in less than a day.

I would suggest that Array Solutions and / or Acom America could have emailed the factory, told them about
the flakes they were talking to on the phone and found out that we were dealing with a known issue. Thus
my suggestion that if support is needed it might not be as close as it would seem at first glance.

My apologies if you take offense to that suggestion but based on my personal experience it is legitimate.

Bill,

While you're correct that on very difficult problems, or especially on
circumstances that we may not have seen before, consulting with Acom in
Bulgaria may be necessary. It definitely streamlines the process by
leveraging their much more extensive and varied experience.

Even so, I'd like to think we're marginally helpful to our customers from
time to time.

Barry,

That is the same file that Acom sent to me so I will not upload it. I will attest that it worked well
in my case. I no longer use it a Flex provided a solution in their latest software.

Agreed - Bill can you share the circuit by uploading with a note to the
Acom Group files section at http://groups.yahoo.com/group/acom-list/files/
?

There's a file in there showing a low pass filter designed by SM6CNN for
his Orion Arc Faults but it didn't come from Acom.

Barry:

You can get one free from Ten Tec if you own an Orion or Orion II. I got one a few weeks ago, but it didn't cure the problem. I'm convinced it's something in the relay timing in the Orion II that goes bad causing a very small arc, or transient in the Orion T/R relay that is amplified and picked up by the Arc Fault sensor. If you do that test I mentioned a few weeks ago, you can prove that. Lock the ACOM in transmit by shorting the keying cable, transmit with the Orion, and when you un-key the Orion, the fault will happen.

BTW, the circuit is a simple Pi low pass filter...a coil and two capacitors.

Bill, that Orion (not Orion II) firmware update that Dick references in
that linked post pre-dates the Arc Fault issues that we've been discussing
here. That rather ancient firmware update was a fix for the Orion keying
loop timing but there was still the low freq RF problem back then as well
as the issue Ron is currently having with the Orion II.

Dick:

Thanks for that information. Ten Tec assures me that all subsequent versions have the proper timing, but I'm not so sure. This seems to be an intermittent problem that only shows up after a few hours of contesting, and mostly on 15 and 10 meters, although I have seen it on all bands at one time or another on various antennas, a dummy load and at two different QTH's. It does not happen when I drive the amp with my old TS-870 into the same antennas.

I'll parse this over and offer some thoughts to TT since they are in the process of updating their firmware for both Orions to version 3.xx.

> has their issues in this area also.

Let me put some color on this. I'm in the tiny minority of people who have written software to interact with the 2000A. Yes, the serial interface is poorly documented. There's only a spreadsheet with tables of command and status codes, plus a few notes. But with very careful study one can piece together how to communicate with the amp. I wouldn't say the serial interface is buggy, but it can be tempermental: the fixed 1200 baud speed is very slow and the interface doesn't appear to be interrupt-driven. So you have to be careful not to bombard the amp with commands.

My code successfully "pre-tunes" the amp for whatever antenna and frequency segment I'm using. Very useful for quick QSY in contests. The auto frequency detect works, but the drive is shunted to a dummy load during tuning, so you lose the part of your transmission that occurs while the amp is tuning (usually one dit or syllable.) Pre-tuning eliminates that.

I also wrote code to duplicate the re-tuning sequence that was in the old AcomTools program: with one click I can re-tune the Acom for all antennas and segments on a band, all antennas on all bands, etc. This code works, but it was a bear to write and debug. There were lots of timing issues and I had to do a lot of guessing about how to get the amp in and out of the autotune sequence. But I worked it out eventually.

This is very advanced stuff that the typical user will never encounter.

The 87A interface is more straightforward, but I've never written any code for to drive the amp because it's not necessary for my needs: the 87A keeps the low power drive connected to the antenna during tuning, so you don't lose any part of the transmission, and AlphaMax takes care of autotuning on the fly. It might be nice to have a nicer GUI than AlphaRemote, but it works well enough and I haven't been motivated to write one.

For remote users, one big advantage of the 87A is that the command set lets you turn the amp on and off. With the 2000A, you have to do it by toggling a pin on the RS-232 interface.

Hope this clarifies things.

My ACOM 2000 has been working wonderful for five years. Same set of tubes and same output gain of 15. The two problems I had was due to a screw connector on the 75 meter rotating dipole all the way up at 114 ft and during the winter. Other problem and why I mention this now is for Yaesu FT2000D owners. The first run of FT2000D units had a voltage spike that even with the output turned down real low presented a spike leading to an arc fault condition and resetting of the ACOM. After four FedEx trips to Yaesu in California and a consultation with Japan, a modification was installed and the ACOM never had an arc fault over the last four years. Joel, K2QBV

Dick,

While I have never actually looked at it with a scope I know that Flex extended the timing slightly and shaped the chop off of the carrier, think the anti chirp shaping on CW. This appears to be a full solution and the extra time must be very short as it certainly is not visible in anything I do. Hopefully Ten Tec can do something similar

Good luck!

Agreed - Bill can you share the circuit by uploading with a note to the Acom Group files section at http://groups.yahoo.com/group/acom-list/files/
?

There's a file in there showing a low pass filter designed by SM6CNN for his Orion Arc Faults but it didn't come from Acom.

Thanks & 73,
Barry N1EU

Dick,

While I have never actually looked at it with a scope I know that Flex extended the timing slightly and shaped the chop off of the carrier, think the anti chirp shaping on CW. This appears to be a full solution and the extra time must be very short as it certainly is not visible in anything I do. Hopefully Ten Tec can do something similar

Good luck!

Dick:

Thanks for that information. Ten Tec assures me that all subsequent versions have the proper timing, but I'm not so sure. This seems to be an intermittent problem that only shows up after a few hours of contesting, and mostly on 15 and 10 meters, although I have seen it on all bands at one time or another on various antennas, a dummy load and at two different QTH's. It does not happen when I drive the amp with my old TS-870 into the same antennas.

I'll parse this over and offer some thoughts to TT since they are in the process of updating their firmware for both Orions to version 3.xx.

Barry:

You can get one free from Ten Tec if you own an Orion or Orion II. I got one a few weeks ago, but it didn't cure the problem. I'm convinced it's something in the relay timing in the Orion II that goes bad causing a very small arc, or transient in the Orion T/R relay that is amplified and picked up by the Arc Fault sensor. If you do that test I mentioned a few weeks ago, you can prove that. Lock the ACOM in transmit by shorting the keying cable, transmit with the Orion, and when you un-key the Orion, the fault will happen.

BTW, the circuit is a simple Pi low pass filter...a coil and two capacitors.

4826. ARC FAULTS

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-14 23:50:56 UTC
From: Steve Tripp (K1IIG)
Topic: 4809 Message: 4826

ALL,

I do not like to get involved with multi threads but feel obligated as I was the first one to have the FLex/Acom Arc fault issue. I worked with Gerald, owner of Flex, for months and jumped through many hoops as I was the only one complaining. Later Bill, ND0B also had the problem and he sure helped out convincing Flex it was just not me. The issue ends up to be a pure timing problem changed in their 2.xx software release. I later went back many versions to their 1.xx software and no ARC faults hence no dropping of the amp. One partial cure was to build a HPF and place in the input to the amp. This greatly reduced the unwanted frequencies below 1mhz and helped but did not cure the problem although it did cure the problem with some radios driving the Acom and other amps. The final cure was Flex slowing down keying and changing their "wave shaping" during keying. In Flex the fix is called "Slew" and works to completely eliminate the ARC fault in the Acom 2000a amp. So ARC faults can be something other than antenna problems but for sure the poor antenna is the main culprit for ARC faults. I confirmed this info this weekend at the Orlando, Florida hamfest speaking with Flex.

If not using a FLex, do try the HPF filter. I built 2 of them in a Home Depot electrical box and reduced the unwanted signal by 45db and with 2 cascaded by 100db with a bit more loss at 160m. Email me direct if you wish a schematic, real easy to build and cost is almost nothing depending on junk box.

Steve
KIIIG at arrl net

I too can confirm the arc faults stopped after Flex modified their software. Before, I had the faults often, but the ACOM handled them with no apparent degradation to the amp/tubes so I am happy about that! I am very satisfied ACOM customer.

Regards,

bob_naumann <W5OV@...>

4828. 2000A ARC Fault and Low Frequency Parasitic problem with some radios - Acom's answer:

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-15 11:34:27 UTC
From: Bob Naumann
Topic: 4828 Message: 4828

As promised, below is the reply from LZ1IU @ Acom about transceivers that transmit low frequency parasitic emissions (100 to 500 kHz).

Background: This problem has been reported primarily in the TenTec Orion and some Flex radio models, and in even more rare cases, some other brands/models.

I have uploaded the file to the Acom group home page file section in PDF format (HPF_Orion.PDF). After doing so, I noticed that it was already posted in Word format by W0YG back in 2005 as HPF.DOC.

So, this low frequency parasitic emission problem with these transceivers, while somewhat rare, has apparently been known for many years (since 2004/2005).

It is also reported that the manufacturers of these problem transceivers have responded and have made changes available to correct the problem.

If you have a radio that has this problem you may want to contact the radio manufacturer for the proper corrective action.

If not, this simple high pass filter shown in the document can be inserted between your radio and the amplifier's RF input to block the low frequency parasitic emissions from those radios.

73,

Bob W5OV
Array Solutions

****
****

Hello Bob,

Please see attached pdf file. Let the customer try using a high pass filter between the transceiver output and the amplifier input - see the attached filter description. It has been very useful against Arc Fault protection tripping unnecessarily with certain models of transceivers which produce (even low level) parasitic emissions in the low frequency band (100-500kHz).

Please inform me again.

73 Stan LZ1IU
Sofia, 15 February 2012.

Yahoo group: acom-list (2010 — 2016)
Date: 2012-02-15 13:36:35 UTC
From: Steve Tripp (K1IIG)
Topic: 318 Message: 4830

HI George,

For some reason I did not put any resistors in my filter relying on the I/O impedances. Without them it works perfect. I built mine into an single electrical box with 3/4" knockouts on each end that take an SO239 chassis mount connector. The coil winding is not critical and you can fuss with the caps to determine the cutoff point should you be able to sweep the filter. Mine started to cutoff just below 1mhz and down around 100khz I was getting aprox 45db rejection.

From: Andrey
Topic: 318 Message: 4831

The resistors are NOT part of the actual filter design!
They are part of the schematics in order to represent the source output impedance (R1) and the load input impedance (R2) in order to simulate the filter circuit in software and calculate the other filter components.

If you terminate the filter with 50 Ohm resistor it will be the equivalent of a dummy load!!

4834. Complete ACOM2000 remote operation with all possible accessories

Yahoo group: acom-list (2010 — 2016)

Hi!
I just wanted to say that I have a complete description of a ACOM2000A
remote operation set-up with all accessories you may need. Works with ADSL (500 kbit/s uplink)and with no problems since 3 months. I needed to decouple heavy RFI from the set-up (DSL and 160 m are not always compatible)and have made a similar description (so far only in swedish).
This might inspire more to go remote. 73 de Kari SM0HRP

Dear K5WK,

I do believe that this switcher is still available. I bought one new from a Danish dealer just a few months ago. I believe he ordered directly from ACOM. I think you will need ACOM 2000SW also.

And I do believe you are aware of the link

Hi Callum,
It's runnig away great need to do some re working of the shack to get everything the way I want it but the amp has worked fine. It great to have that little bit extra power when required to make the contact and saves having to run the rig flat out. Great to get to leagal limit with 25 watts from the rig.
It took a while to get the amp tuned to all the band's I normally work on but the setting are duly noted and now set up is real quick.
Really enjoying it.

4859. Simple Home Brew Filter

Yahoo group: acom-list (2010 — 2016)
Date: 2012-03-01 01:44:01 UTC
From: Mark Mumaw
Topic: 4859 Message: 4859

I was having constant problems with Arc Faults when using my 2000A with several Vintage SSB rigs. I built the basic filter designed by SM6CNN with minor modifications. I used 2000 pf caps instead of 2200 because that was what I had available. It took about an hour to build this from my junk box.

I posted to the file section both a photo of the simple home brew filter along with the trace from my spectrum analyzer. As can be seen from the screen trace, the response was similar to what was noted by SM6CNN.

This filter totally solved the problem.

4860. ACOM 2000A Misbehaving

Yahoo group: acom-list (2010 — 2016)
Date: 2012-03-02 01:14:24 UTC
From: ve3cfk
Topic: 4860 Message: 4860

I've owned my Acom for 5 years now.
Within the last month, it would kick-off for no apparent reason, and not provide a fault message. It kicks me off (doesn't matter the band or antenna) if the SWR is close to 1:1, but operates just fine if the SWR is 2.5 ! The gain is sometimes 13 db, but mostly 10db. When I try to tune the amp for any band segment it says VSWR too high, even when my ALPHA 4520 says it's 1:1.2

Any help would be appreciated.

Chet, VE3CFK

4861. Acom filter cleaning reminder

Yahoo group: acom-list (2010 — 2016)

From: kamarty456
Topic: 4861 Message: 4861

Well for those of you who need a reminder.....
You should clean your ACOM fan filter on a regular basis.

For you lazy folks, at least do it twice a year when you
adjust for daylight savings time as well as replacing your smoke detector batteries.

Keeping the air filter clean will ensure efficient operation of your amplifier.

I purchased a Acom 2000A from a friend but the Acom Tools is on a Floppy disk. Problem. I don't have a Floppy drive.
If someone has a copy I would appreciate a zipped file.
If all fails I will contact Array Solutions or K1LZ in the morning.

4870. Acom with boat anchor?

Yahoo group: acom-list (2010 — 2016)
Date: 2012-04-12 15:06:13 UTC
From: m5zzr@btinternet.com
Topic: 4870 Message: 4870

Hello Group.

I've been using my 1000 for 2 years now with my 756PIII. Brilliant.

In a quest to get back to my roots I've just purchased an FT-102 as a project radio. If possible I would like to give it a go with the Acom at some point but of course the Acom has no AGC output. I understand I can apply a negative DC voltage to the 102, although I'm not sure how many volts. Does anyone have any tips or is it a bad idea to drive the Acom with a 102?

Thanks. Mel. M5ZZR.

Ill echo W5OV. Disconnect your ALC and throw the cable away. Drive the amplifier within its linear region and you don't need ALC.

Topic: 4871 Message: 4873

I think he is asking how to reduce the power of the FT-102. 100-110W input is not so healthy for the ACOM. To reduce the power of my Kenwood TS830 I used a 9V battery and a 100K variable resistor. ALC is usually between -1 ~ -4V to regulate between 100 - 0 Watt. Just try with the 9V battery and var.resistor.

The FT-102 does not have a "fixed" output of 100w.

Turn it's DRIVE control down to reduce the output. Using ALC to do so is
asking for trouble - distortion, etc.

Thanks Bob, Hal & Ger. I don't pick up my FT-102 until next week hence the reason for not knowing my way around the radio yet. Sounds like I should be able to cope one way or another. I used to have a 520S in the past used the 9v battery solution which worked fine.

I take your point though Bob that it may not be required. I am interested though - Why would the ALC cause distortion?

The DRIVE control on the front panel of the FT102 is intended for this purpose and it is the proper way to keep the output level down. Check the FT102 manual for a description of the DRIVE control.

Using ALC to do so would be like keeping your foot into the accelerator of your car keeping the engine at high RPM but applying the brakes (ALC) to control your speed - just take your foot off of the accelerator (reduce the drive).

Great news for those who want legal limit power without the need of
automatic tuning and therefor lower price ratings (I might hope).
I love my Acom 1000, seems that Acom used the known led bar features plus
new tuning aid like the 1010.

Oscar, if you look at the photo of the Acom 1500, you will see two tuning knobs. You must adjust these knobs to tune the amp. It is not automatic..

I have an Acom 1010 which tunes with the two knobs, and tuning is very easy.

If you want fully automatic tuning, the Acom 2000A may be what you want, but it is mucho denaro! Hi.

More likely your email address has just been harvested by a SPAM-bot, which then sends out general info appearing to have come from you.
I havn't seen any good solutions for this other than to change your email address.

From: dj0qn
Topic: 4883 Message: 4891

There are two solutions to turn the 2000a on remotely using its serial port. In this case, the main power must be on, but that only powers the ECU. You will need a solution like you mention below if you want to turn the full power on and off.

These are the two solutions:

1) The "Remote Power-on Adapter" available from Acom dealers. This fits on the back of the 2000a and allows a software client such as Acom Tools or TRX-Acom to turn the 2000a on and off. Since this uses a serial port, it needs to be used either by using a remote PC, or a serial server, such as those from Lantronix.

2) There is a stand-alone device available from RemoteRig called the RCH-1216H. This device has a built-in web server, so no external serial PC or server is required. See http://www.remoterig.com/wp/?page_id=1010 for details.

I wonder why they have decided to make the ACOM1500?
You'd think a newer 2000A version with newer tubes?

On the other hand the 2000A is indeed perfection !!!!!

It looks like an update of the ACOM 1000. With the GU74b no longer in production, the amplifier companies seem to moving to the 4CX1000 which is what Alpha did recently. I wouldn't be too surprised if the 2000A gets a pair of those tubes and re-emerges as an ACOM 2500 or 3000.

GU74B is still in production and will be while it is used in the Russian
military and commercial communication equipment.
But it's not good to rely on one tube only. It's better to have more
suppliers, amplifiers and power levels.

This rumor about "GU74B no longer in production" is kind of annoying. It keeps resurfacing all the time inspite of the announcements made by ACOM and Array Solutions. All started a few years ago when there was a shortage and it is now like the gum stuck on your shoe - you just can't get rid of it. People should check their facts before posting.

Thanks Andrey.

This whole thing is very puzzling to us as well. Some people seem so definitive but yet, the authorities (Acom, Svetlana) say otherwise. Also, the misconception that when a tube was manufactured makes any difference whatsoever is puzzling.

When people ask me about this tube not being available, I ask them "how many would you like to purchase"?

We have them, Acom has them, and Svetlana will make more. Yes - they are very, very expensive (>$1k each) now for brand new tubes. Acom hedged this price increase and purchased a warehouse-full of GU74B (4CX800) tubes some time ago.

However, the fact is that once a tube is manufactured, it becomes "new old stock" almost immediately. But, the date code on the tube merely shows when it was made - it has no other meaning or value. Tubes do not "go bad" sitting on a warehouse shelf. There are debates about taking precautions with tubes that have not been used for a long time, but that's beyond the scope of this email.

In the case of Acom amplifiers, every tube is fully tested and has a brand new warranty on it based on the date you purchased it - not the date it was manufactured.

The NOS matched pairs of tubes that we stock and sell here are tested, measured, and matched based on these measurements, and you receive the full documentation of the data for each tube.

In service, these tubes are extremely rugged and will last a long, long time if not abused. Sure, there might be a defect that may have to be dealt with, but defects are truly rare. Most Acom owners' experience is like mine - my 2000A was purchased back in 1999 and it still has the original tubes and they work just the same as they did when I got it.

Check our web page for more information from Acom and from Svetlana (sorry, only in Russian).

4897. ACOM 2000A Major Repair

Yahoo group: acom-list (2010 — 2016)
Date: 2012-04-27 14:45:24 UTC
From: ki4ge
Topic: 4897 Message: 4897

Kudos and thanks to Jay Terleski at Array Solutions for a superb repair on my ACOM 2000A which required removal and replacement of the entire band switch and tank circuit assembly as well as replacing its driver board. The amp was been performing great since getting it back about 2 months ago.

The band switch had been arcing, apparantly due to a undetected failure in its driver board, which was not not known to me because the amp is used in an internet controlled remote station and the arcing was not detectable. The amp was producing full power until the problem was finally detected after the amp began to alarm with a load capacitor malfunction; unfortunately by that time the band switch was burned up.

This was a major and challenging repair and special thanks to Jay for his hard work getting the amp back to the excellent performance I have always enjoyed from it.

I am very pleased with the service at Array Solutions.

73. Jerry, KI4GE

4899. For ACOM hv transformer is not ready to live more than 5 years !

Yahoo group: acom-list (2010 — 2016)
Date: 2012-04-28 08:26:19 UTC
From: moumoumousse
Topic: 4899 Message: 4899

I am not agree with ACOM.

The HV transformer is out and I spend 500 euros for repair.

My 25 years old TL922 is always in life. Before YAESU 2277Z, and before FL2500. No problem with, only I changed two time 3-500Z with TL922 during this period, one time 572b with Yaesu. In the same shack of ACOM 1000 now.In the same condition of temperature, humidity or what else ?

I know that many others people have problem with the transformer. I received other mail for that. Vince in England know also the problem.

I am not a contester and never replace the original tube. I think that there is a big problem with the production of this transformer and his fiability.

It means that a transformer need to be remplaced every 5 years !

See the mail from ACOM service :

" According to us, the product defects appear before the first year to expire.
We provide two calendar years warranty. Francis, you have used this transformer
3 and half times longer. Consequently, we think that this fault is a result from
operating conditions - increased humidity, increased ambient temperature,
increased mains voltage, any power supply over voltage, etc."

I am in France and my shack is in my house. All the conditions are good to use an amplifier. So this reply is not good.

Sorry for that because ACOM 1000 is a very good amplifier, very quiet and very nice to operate. But ACOM service is very bad and don't want to recognize this default. Not ready to buy the new ACOM 1500 !

Please tell me if you have also the same problem.

Best regards

Francis **F6BLP**

Francis,

I can appreciate your disappointment that the ACOM 2000A transformer has apparently failed. But I think that to hold ACOM responsible for the failure and to consider replacement beyond their very good warranty is an unreasonable expectation. Electronic and mechanical components do have a variability in material and manufacture that sometimes results in premature failure. I am sure you have experience that in other things you have purchased.

A transformer on the other hand should be one of the more stable and long lived components in electronic applications. You did not describe the type of failure that occurred. Was it a 'open' winding, or a winding insulation failure and voltage break down. The exact type of failure can be of value to the manufacturer and influence his choice of materials and processes.

If I were ACOM, I would offer a replacement transformer at my cost, and the return of your failed transformer so I could analyze the nature of the failure.

Otherwise I think ACOM's position is correct given the number of years it was in service, should it last longer, yes, but it did not however it did perform as advertized for the warranty period.

Things happen, and they become 'your' responsibility.

Regards,
Norm W4QN
A owner of an ACOM 2000A since 2007 - hope your 5yr life is an anomaly.

Actually the transformer in my 2000 failed and had to be replaced after 6 years of use and outside the warranty period. Although I wasn't happy about the failure I am still very pleased with both my 2000 and 1000 and would be hard pressed to replace them with something else.

HI Norm

Thank's for reading me.

The problem is a HV winding insulation failure ... My dealer send the transformer to ACOM in the end of 2011 for expertise, and without any reply last week from ACOM I ask to have some news ! And on my post is the reply from ACOM.

In the same time, few days ago I received this mail from a M0... in England :

" I have an Acom1000 and have the same problem you had, the transformer is leaking to earth,(700V on the case), sent to dealers repair people and they have just replaced transformer in another acom1000 with yet again same fault. Acom have said its not a design fault, as its lasted a few years and if it was a car you would expect problems, i'm quite disgusted with ACOM responce."

So I think that there is a real problem !

Best 73/DX Norm and excuse me for my poor English !

Francis ** F6BLP/6W7SK **

Hi Francis,

I did error in thinking you had a ACOM 2000 instead of a 1000, however my comments would apply to either. A high voltage insulation failure can have several causes. Poor or defective insulation material, improper application of the insulation and maybe the most significant is inadequate vacuum impregnation of the high voltage dielectric compound. Besides creating some interwinding voids which reduce the breakdown voltage, the inadequate sealing of the core/windings allowing moisture to be drawn into the windings as the transformer temperature cycles from operating or just atmospheric changes. The operating environment may contribute to that type of premature failure. One other possibility could be a power surge of the mains supply - that transient can create a significant over voltage peak damaging the insulation.

Having designed,and assembled HV transformers I know that poor vacuum impregnation or operating in high humidity can lead to HV winding failure.

From your comments it appears you have made the somewhat costly repair by replacing the transformer. Hopefully it will give you many years of service.

Good luck,

Norm W4QN

4907. optional cooling specifications

Yahoo group: acom-list (2010 — 2016)

From: kamarty456
Topic: 4907 Message: 4907

I am unable to find any specifications for the optional fan.

I wonder:

1. what is the rpm at low and at high speed?
2. what is the CFM at low and high speed?
3. does the factory optional fan have a bearing or do they use a bushing?
4. how many blades does the fan have?

I already have an optional fan installed and I believe it's one from ACOM, but I do not know the specifications.
The fan is a 24VDC type connected to the 2000A control board...
the small circuit board specifically for the fan.

My fan does run two speeds low and when the exhaust temperature
is [I think] over 90c the fan runs at high speed.

This is for information only I DO NOT have any issues with my external fan or the 2000A itself. My 2000A is around eleven
years old and is perfection! I'm the original owner.

I also clean the dust filter frequently to ensure maximum air movement. It's dusty here in Arizona!

I cannot tell you when they will be available for purchase, but we will have one on display and operational with a 2000A in our booth in Dayton.

Come and check it out along with the new 1500 amplifier.

4913. Question after repair ACOM 1000

Yahoo group: acom-list (2010 — 2016)
Date: 2012-05-17 10:04:18 UTC
From: Ger
Topic: 4913 Message: 4913

Hello all,

Last week my ACOM 1000 blows the main fuse of the 220V group on where the ACOM connected on. The ACOM was powered on but in stby mode. After resetting the main fuse, I switched on the ACOM 1000 again and immediately there was a very loud firecracker bang. After that the ACOM came on with PN07 auto-protect. After inspection it turned out that HV capacitor C10 on the HV board was exploded! This is a blue disc capacitor of 2N2 Nf 10 Kv. Also fuse F2 (2A) was blown.
I did sent an email to ACOM factory in Bulgaria and ACOM did sent me two replacement capacitors for free. Still excellent service from ACOM!

Now my question: After replacement of capacitor C10 and Fuse F2, everything works fine again: same output, same HV etc. So it looks like C10 was the cause of blowing the fuses as it short circuited the HV.
After I power off the ACOM with the front on/off button, I hear after 5-6 seconds, the sound of, most likely, a relay which get de-engaged.
This happens all the time after 5-6 seconds when powering off the ACOM 1000. I don't know if that happened (falling off relay sound) before the cap exploded. So can someone with an ACOM 1000 confirm if you hear a sound after 5-6 sec when powering off with the fron on/off button? It's not loud at all so you have to listen close by.

Thanks and best 73's Ger PE1CZG

Hi, I am an happy owner of an Acom2000a since may 2004.

I replaced the valves in my Acom 2000a So I suspect a short circuit between the cathode and a grid of two old tubes.

I had to change the valves because the internal voltage tab was set on the 220v, probably the voltage too high on my line has shortened the life of the valves

Whereas the tension on my line is 238v Now I have chosen to place the tab on 240v. When the amp transmits the voltage drop to 232v.
Any suggestions on how to set from the RCU the menu 5-6 (from the user's manual)LOW NORMAL HIGH?
Many thanks,
Massimo iz5asz

4916. Acom 1011 Mod

Topic: 4916 Message: 4916

Hi all,
I recently buy an Acom 1011 amplifier, it doesn't have the power in protection mod done, I have the board to do the mod but I don't have any schema or instructions
*
*
Can anyone help me??
*
*
*Thanks
*

The attached is in English, but it has very good full color photos, so you should be able to perform the installation.

From: iz5asz
Topic: 4928 Message: 4928

Hi, I own an Acom 2000a.
The question is: the mains at my home is 230v.
The filament volt from the RCU is 12.3v and on transmit drop to 11.5v.
What will happen to the tubes considering that the nominal voltage of filament is 12.6v?
73, Massimo

Hi Francis,

I can imagine, yes.

However, as long as the faulty components will be replaced under warranty and amp is returned in a good working order, I would say "it can happen". Do bnot get me wrong, it is sad that it can happen, yes sure.

Let us know the progress of getting this issue fixed.

SB26 indicates a plate current error during standby.

According to the error message, this does not seem to be related to the
problem you had previously with the power transformer.

4936. Acom 2000A - two questions

Yahoo group: acom-list (2010 — 2016)
Date: 2012-06-08 08:24:55 UTC
From: Kjeld Holm
Topic: 4936 Message: 4936

Dear all,

I have two questions which I have not (yet) found an answer to in the manual.

1) Do I "wear out" my Acom 2000A more in the mode OPR than in the mode STB when sitting long hours waiting for the next DXCC entity to show up?

2) At which power level can Acom 2000A run "key down" forever? And how to calculate this? I see in the manual that transmitting with 1500 watt in x minutes is OK followed by a pause of x minutes. But I just wonder if one could at reduced power transmit forever.

Best regards

OZ1CCM Kjeld

A 35 cfm fan can dissipate about 20 watts per 1 degree rise in Celsius degrees. Don't know what the standard fan is. But assuming this and say 20 degree ambient and 90 degree max air temp that's 1400 watts dissipation.

Efficiency drops when you run at lower power, other variables etc.

I'd be surprised if you couldn't run it at 600 watts continuous RTTY output but just a guess.

Topic: 4936 Message: 4938

Hello Kjeld,

/1) Do I "wear out" my Acom 2000A more in the mode OPR than in the mode STB when sitting long hours waiting for the next DXCC entity to show up?/

No, you will not *wear out* your 2000A when he is in the OPR mode for a long time. In that case my 8 years old 2000A would have died long ago... ;-)

/2) At which power level can Acom 2000A run "key down" forever? And how to calculate this? I see in the manual that transmitting with 1500 watt in x minutes is OK followed by a pause of x minutes. But I just wonder if one could at reduced power transmit forever./

Probably no one has ever tested this before. If the temperature of both the tubes remains acceptable IMHO it will be possible to key-down the amplifier for a very long time. And the 2000A has a very good protection; read the manual and in-depth details from Acom. You will probably understand that the lifetime of your tubes will decrease, when you operate the 2000A in this way. And, *forever* lasts nothing, not even you and I... ;-)

Good luck and 73, Hans.

4939. Re: Acom 2000A - two questions

Yahoo group: acom-list (2010 — 2016)
Date: 2012-06-10 17:38:08 UTC
From: Norman
Topic: 4936 Message: 4939

The max key down continuous power limit is an interesting question that probably can not be proven short of doing such a life test which would likely be destructive depending on how long is 'long'.

But some comparative analysis may give a clue. One case would be to compare the near equivalent models of ALPHA amplifiers who regularly advertize a "Brick on the Key" performance. There is a historical relationship between Alpha and Acom and the component and design execution appear virtually the same even now. So I think we could assume air flow and pressures would use similar design criteria and if the blower specs on an ACOM are comparable t an ALPHA and the tube choice is of the same class you would have the same results as an ALPHA, put a brick on the key and forget it.

Also consider most tubes used in amateur applications are/were used commercially in FM or AM transmitters, Commercial two-way repeaters, and other industrial applications who regularly ran in continuous duty conditions. And we hams often used those "pulls" to build our amplifiers with good results.

What the likely failures in a long time key down application. The tube overheating because of inadequate air flow a key one, but don't forget a under designed plate transformer that also can overheat and have an insulation breakdown, then there are the RF coupling capacitors that can be damaged by overheating as well which in turn cause a transformer to fail. A lot of assumptions have to be made about equivalence in components to the ALPHA model, but I think that maybe both companies may have gain some knowledge that would tend create a high degree of equivalence.

However I would not subject my ACOM 2000A to such a test as the risk is too high, and if it survived a long time key down test that information is of no value as it would not effect how I use the amp in amateur service.

The first question how ever has more interest as it is a common situation that the amp is in standby for many more hours then in the transmit state. Although there are many components with various voltages applied, the tubes primary wear out element would be filament/cathode life. Anytime the filament is energized there as to be some degree of depletion going on. But again commercial service would suggest there is normally a very long life to be expected. In fact it the other argument that turning filaments on and off is more damaging to tube life then continuous operation. Another age old argument, leave the equipment on continuously or turn it off at the end of use. I am sure there is statistical data to support one or both of those arguments.

Hi guys, does anyone have an Acom 1010 and wants to share experiences with it? Mine is just one week old and I am very pleased with it although I can't get more than 800W PEP. I have seen some youtube videos where all of them show over 900W with 85W in. Maybe its because I am running it at 120VAC and the plate voltage drop too much,anyway there is no way to read that voltage trough the LED's. Your advices and suggestions will be welcome, thanks

Hector,

The Acom 1010 is not supposed to be run at more than 800w output.

You might be able to squeeze some more out if you run it on 240, but you'd be violating the manufacturer's recommendation for the amplifier and no one can tell if you're running 800w or 900w anyway.

If you want more power, you might want to upgrade to a 1000 or perhaps a new 1500. We expect to be shipping 1500's right around the 4th of July.

Also, make sure you do not have the internal tuner turned on in your K3 - this can reduce your drive level too,

And never, never use an internal radio tuner into an amplifier's input. This can damage an amplifier's input circuits.

I am glad I have seen this. I am about to invest in a new transceiver,
and it will be used with some form of linear amp. Some transceivers
offer an internal ATU as an extra cost option, some Ten-Tec's for
example. If I intend to use a linear is this a pointless option, and I
could save money by using my existing, if elderly, Yaesu FC-902 ATU on
the occasions I want to run without the linear? Has pricing been
published on the 1500 linear yet Bob? Thanks.

Sometimes, having the internal tuner is convenient - so you don't need an external tuner for those cases when you run without an amp and need a tuner.

The 1500 is priced @ $4750 and is now approved by the FCC for sale in the USA.

We will get our first shipment at the end of June/ beginning of July.

Most amp will vary with the band your using 10 meters will be your lowest output and 80 meters or 40 should be 900 . I run both 2000A and 1000 and these amps always do better on the low bands.

Good morning dear Bob and thanks for your advice. I was just curious but actually I am driving it with just 65 wts from the K3 and I see between 700 and 750 WPEP with my voice and for CW I drive it with 50W to see around 500 out. I have been thinking in the new 1500 but not for now. I still need to run that 240 V line to the shack. I am going to enjoy this very quite 1010 till next year.

Hector,

The Acom 1010 is not supposed to be run at more than 800w output.

You might be able to squeeze some more out if you run it on 240, but you'd be violating the manufacturer's recommendation for the amplifier and no one can tell if you're running 800w or 900w anyway.

If you want more power, you might want to upgrade to a 1000 or perhaps a new 1500. We expect to be shipping 1500's right around the 4th of July.

Also, make sure you do not have the internal tuner turned on in your K3 - this can reduce your drive level too,

And never, never use an internal radio tuner into an amplifier's input. This can damage an amplifier's input circuits.

Subject: [acom-list] Acom 1010

Hi guys, does anyone have an Acom 1010 and wants to share experiences with it? Mine is just one week old and I am very pleased with it although I can't get more than 800W PEP. I have seen some youtube videos where all of them show over 900W with 85W in. Maybe its because I am running it at 120VAC and the plate voltage drop too much,anyway there is no way to read that voltage

trough the LED's. Your advices and suggestions will be welcome, thanks

Hector

This 1010 has a perfect input impedance at 50 ohms with the carbon resistor than I dont need to use the radio tuner in any band.

From my Android phone on T-Mobile. The first nationwide 4G network.

Bob Naumann <W5OV@...> wrote:

Sometimes, having the internal tuner is convenient - so you don't need an external tuner for those cases when you run without an amp and need a tuner.

The 1500 is priced @ $4750 and is now approved by the FCC for sale in the USA.

We will get our first shipment at the end of June/ beginning of July.

I am glad I have seen this. I am about to invest in a new transceiver, and it will be used with some form of linear amp. Some transceivers offer an internal ATU as an extra cost option, some Ten-Tec's for example. If I intend to use a linear is this a pointless option, and I could save money by using my existing, if elderly, Yaesu FC-902 ATU on the occasions I want to run without the linear? Has pricing been published on the 1500 linear yet Bob? Thanks.

The new 2000A RCU is in final testing - we had one in Dayton - and we
expect them to be out later this year.

Pricing is expected to be in the $900 range.

4955. Re: [acom-list] Acom 1010

Yahoo group: acom-list (2010 — 2016)
Date: 2012-06-14 16:59:59 UTC
From: W5OV@w5ov.com
Topic: 1162 Message: 4955

Well, that will be the question most asked.

Here we go:

1) The new RCU allows direct integration with your radio (CIV, CAT, etc.) for tracking as you tune instead of requiring you to transmit to QSY the amp.

2) All connections (except RF) will go to the new RCU and not to the back of the amplifier. This will make remote mounted use of the 2000A a bit simpler from a wiring perspective.

3) Displays many parameters at one time on the beautiful full-color TFT screen so you do not have to navigate numerous menus to get the information you may need.

You can see it here:

http://www.arraysolutions.com/Acom/whatsnew.htm

So, as you turn the dial on your radio, you'll see the frequency updated on the new RCU and you'll hear the amp re-tuning as you cross the band segment boundaries without requiring you to transmit. This will also make the use of the Acom coax switch more sensible as it will follow the radio instead of switching after you transmit on the "wrong" antenna to send the amp to the new band, and at the same time switch to the correct antenna.

That's too bad - the Acom 2000A we had operating in the booth was using the new RCU - it's really very nice looking.

I think it's going to be very popular as it does improve the 2000A - and it will work with any vintage 2000A - even the oldest ones - like mine.

4958. RE: [acom-list] Acom 1010

Yahoo group: acom-list (2010 — 2016)
Date: 2012-06-14 19:07:10 UTC
From: Ron N0AT
Topic: 1162 Message: 4958

Hector,

I have been using an Acom 1010 for six years. I have found it difficult to obtain rated output when running it at 120 VAC. It likes to be run with 240 volt mains voltage.

I take the amplifier with me on my contest DXpeditions. When I□m forced to run it at 120 VAC, I keep the output at 600W. Otherwise I run it at 700 watts.

Subject: [acom-list] Acom 1010

Hi guys, does anyone have an Acom 1010 and wants to share experiences with it? Mine is just one week old and I am very pleased with it although I can't get more than 800W PEP. I have seen some youtube videos where all of them show over 900W with 85W in. Maybe its because I am running it at 120VAC and the plate voltage drop too much,anyway there is no way to read that voltage trough the LED's. Your advices and suggestions will be welcome, thanks

Hector

4959. Successful replacement of GU74b in Acom 1000

Yahoo group: acom-list (2010 — 2016)
Date: 2012-06-15 15:34:43 UTC
From: John
Topic: 4959 Message: 4959

My Acom 1000 is roughly six years old. About six months ago the maximum output power dropped to about 700 watts, over a period of several months. With the encouragement of Charlie, K2BU, I contacted Array Solutions and discussed with Bob the field replacement of the GU74b final. Array Solutions promptly shipped me a replacment tube, and following the instuctions I had found on the WEB, I swapped the old tube with the new one.

While holding my breath I applied power, waited about ten minutes and then applied RF to the input. The amplifier now gives me the full 1000+ watts output. The expression "it was a piece of cake" certainly applied to the entire operation.

John, thats great. A friend near DC has a 2000A and his results do far have been unsucessful. He sent it to the service center in Mass. By Fedex on April 2nd and still has not received it back yet. He just phoned me and said they have replaced the tubes but when turned on it shuts off and he was told they have not figured out whats wrong with it yet. He added that he has called them several times and has been told they would call him back but they never do. He always has to initiate the call.

This same amp was repaired by Acom Ma. a little over a year ago and the story was different, a quick two day turn.

He sure is not a happy camper.

I had told him to sent it to Array Solutions for repair. I think he now wishes he had sent it to them.

My experience as of a few years ago. (may have changed since then).

Beware that these tests don't test for a full KW out -- like the
ACOM-1000 is capable of.

Last I dealt with him, the tests were limited to about half kw.
Keep in mind power limit in UK is 400 W.

Depending upon what you are expecting, he is a reliable provider and
stands behind what he sells.

I never did get a tube from him that did a full KW in an ACOM-1000.
800-900 watts maybe with higher than normal drive and grid current. I
settled for this third try tube. The two I send back did 600 watts at
normal drive levels.

Hi

I have a problem in my Acom 2000 A, starting "operate", the display shows "G 2 too low" 214 v.
The famous capacitor C2 was changed 3 times, but the problem after few time (about 2 months and not after a lot of hours of run)
reappears. Changed also the tubes, but also the originals were good.
The problem returns to restart after a smooth operation.
Does anyone have an idea of what could be?
Many tnx 73 de iv3jcc Gianni

The Acom2000 is very sensitive on unstable (to low) mains voltage, voltage may be different during daytime, depending on your power provider's quality. Had the same problem at a remote location and had to solve it with a mains stabilizer.

Never had that silly g2 message again...

Hi,

I have one 2000A with a problem on BIAS.

After 2 seconds of power on, the LCD shows a message that bias is too low
-085 Volts and the amplifier turn off.

Any glue to this?

Thank you,

Marcus - PP5MS

Yes. I belive your answer, but here the voltage is 235 and stable.
Tnx 73

Hello

I had this one time.
It was because i let the main switch ON.
Now i’m puting always the main switch off and no more messages.

unplug the amp from sector and let it 10 min and test again

From: ny9h
Topic: 4981 Message: 4981

the 20 amp dual 240 volt breaker was opened.

the front pwr switch was on .

I read 6.4 ohms across the plug, WAY too much current.
Disconnecting the LV low voltage XFMR primary from the mains control board opens up the 6.4 ohms.
Looks like the primary is shorted... but pins 1-3 shows 2.3 and pins 4-6 show 2.3 ohms.
both sides read the same ??? I guess if a surge broke down transformer , would the two 120 sides of the primary read the same?

looking over what I have from the 43 page tech notes,
i don't see anything else that would cause such a low r value....
I hate shipping this box, esp since i don't see the HV XFMR box here.

any ideas or comments.

So far it 'appears' my smaller solid state amp survived on the same 240 line,

Jay was kind enough to give me some guidance, but i dislike going back for more 'free' help. And "" I'd rather do it myself""

N2EHG

Good to hear from you and I have a good answer for you.
Many like to reduce the power from the 102 so that it does not overload a linear's input. People have tried reducing the drive and that works fine on CW and continuous output modes but the drive control has no effect in regular sideband. Some have used the ALC connection to their linears and that is a lot better than the drive control on SSB but because all ALC circuits have a time constant to deal with the first syllable of words will overdrive the linear and cause splatter. So here are two solutions:
1. Reduce your loading control by turning it completely counter clockwise to the first stripe or marking and dip the plate for minimum plate current. This will yield about 60 watts of power. If you need more power advance the control 1/2 towards the next mark. The second mark will yield about 90 watts and the next 120. At about the third marking you should develop full power. So by adjusting this control you can vary the power output from about 55~60 watts to full power with no overshoot as you would get with the ALC control on the back of the radio. This is my preferred method and will have the tubes last you for decades and give unbelievable low transmit distortion. What you are doing with this method is decoupling the finals from the antenna load.
2. This second method should also work fine and will give you even lower power outputs. First tune for maximum output on the band you are considering as maximum power output is usually the place of highest efficiency. Then on SSB engage the processor. Listen in the headphone jack while adjusting the compression control until the audio sounds identical to the unprocessed audio. If you wish you can bring it up to develop some processing as well (but for the purpose of this theoretical discussion make it sound the same). Then with the processor on you will notice that the drive control does work normally like the C.W. modes and you can turn the power down to almost nothing.
If I had the time I would publish this to my 102 website www.members.aol.com/NC4LMal but I don't have that luxury now. So if you would not mind, please spread the word about this and convey the contents to friends and people who might want the info by email or whatever other methods you can muster up.

73 de NC4L Mal

Hope this helps N2EHG

From: Mark Mumaw
Topic: 4981 Message: 4983

The resistance across the primary sounds OK to me. Mine measures 5.5 ohms at DC. I would check the transformer using a Variac. One way is to remove or just disconnect the xformer. Feed voltage from variac into primary, starting with just a few volts. Measure the HV, LV and filament voltage AC on the secondary. A simple calculation will tell you if output voltage is in the ball park. ie for variac voltage of 2 VAC .... 240/2 x measured Secondary voltage will give you the approximate secondary AC at 240 volts of each winding.

If the primary is shorted then the 2 VAC from the variac will do no harm. Also you can put a current meter on the primary and watch the current. It should be very low unless something is shorted.

The secondary voltages according to the schematic is 2050VAZ, 310VAC, and 40 CT AC.

Good luck....Mark NU6X

Is the 2000a the only damage you suffered? Be on the lookout for additional damage, especially if lightning was part of the mix at your place. If other things were damaged, you might be in the range where a homeowners insurance claim makes sense. 73 Jim K1IR

I carry an insurance policy specifically for the Acom 2000a And an icom 7800;
which includes electrical failure,,,

Lost router, raid system ! ; telephone, tv set , computer

It has been pointed out that my DCr measurements
Are not AC... Thus the xfmr might be fine....
Guess my variac comes to play, too bad it is 600 miles at the old house in Illinois.

Due to the potentials of a complex failure it may not wait for me..but rather it may take a trip to
The fix-it shoppe.

Bill

Most repairs I conducted were due to the fact that the air-filter was not cleaned and the limited airflow ultimately did not cool down enough the tube, especially when in use with digital modes. I have seen / cleaned multiple air-intakes fully blocked by dust.

Two Acom 1000s we own, one tube lost its RF power gradually over a period of three years, whereby the higher HF frequencies suffered the most. Replaced by an NOS 1980 year GU74B tube and is running just UFB for two years now.

I also noticed that GU74B tubes which has consistantly been exposed to an high SWR often 'dies' much earlier compared to tubes used at low SWR ratings.

Just my two cents.

Hi Martin,

The first tubes failed at 6K and 6.3K hours of filament life. Got an alarm that there was resistance between the cathode and grid. The tubes still had good output when I replaced them.

Cut the tubes apart. What I noticed with both tubes was when the cathode was covered with a white insulating material the upper portion of the cathode did not have a coating. With the grid extremely close to the cathode I am surmising when the cathode got hot there was some mechanical movement which caused a resistance reading between the grid and cathode.

So, not sure if this is a manufacturing issue with these two tubes. Will have to see when the next one(s) fails to cut apart (different year) to see what the cathode looks like.

By the way the anode was bright shinny copper. Some 8870 series I have cut apart had black anodes and "chunks" missing out of the cathode. Not sure what that all means - just an observation.

Hi George.

Forget cutting the ceramic.

I used a hack saw to cut the metal above the insulator. The anode lifted off.

Tony, very interesting that you investigate a failed tube. Curious to know how you safely "cut the tubes apart"?

Hi Martin,

The first tubes failed at 6K and 6.3K hours of filament life. Got an alarm that there was resistance between the cathode and grid. The tubes still had good output when I replaced them.

Cut the tubes apart. What I noticed with both tubes was when the cathode was
covered with a white insulating material the upper portion of the cathode did not have a coating. With the grid extremely close to the cathode I am surmising when the cathode got hot there was some mechanical movement which caused a resistance reading between the grid and cathode.

So, not sure if this is a manufacturing issue with these two tubes. Will have to see when the next one(s) fails to cut apart (different year) to see what the cathode looks like.

By the way the anode was bright shinny copper. Some 8870 series I have cut apart had black anodes and "chunks" missing out of the cathode. Not sure what that all means - just an observation.

73,

N2TK, Tony

I am getting close to 5000 hours on my tubes in my ACOM 2000A

The amp is working flawlessly!

I was wondering how many of you are at 5000 hours or more run time
on your tubes?

Also..at what run hours did you replace your tubes and for what reason?

I have the ICE 338 AC 240VAC 30Amp line/EMI filter.
The unit is essentially maintenance free. all you do is
replace blown fuses if it does get a hit.

The manual is a single sheet of paper folded in half so
you have 4 pages of information:
introduction, Design, Installation, and maintenance

Go to www.morganmfg.us for information as they have
picked up some of the ICE line. The rest is at Array Solutions

Hello, I am new on the group and I need some help.

I have an ACOM 1000 which turns off for in my view no reason. Only "ACOM 1000" is in the display.
Sometimes, when the timer near to the end for warm-up, the amp shuts off.
I turn it back on and all is okay for a few minutes, but after 5 or 10 minutes it shuts off again.
This happens sometimes 3 or more times a day, sometimes in works fine for a week.
Any help?

Rene, PC2C

Rene: I had a problem with my ACOM 2000A that might be like yours. It turned out to be one of the two interlock switches that shuts down the power if the cover is taken off. The arm on mine was not quite bent far enough upward for the switch to trigger when the cover was put back on. The amp would go through the start-up, but as soon as the timer reached zero, the whole thing shut down. Yours may be just on the edge, and small temperature changes may be causing it to turn on and off. Simply bending the arm up a little bit higher fixed the problem.

Just a guess!

Paul you're correct, a lightning strike is devastating!

The ICE surge protector will address power line spikes that
may cause a hick-cup within the electronics of the amplifier.

I have surge protection on my LCD television, computer, ALL
my amateur equipment etc.

I wrote an email to ACOM. Got an answer within a day!!! GREAT

Hello,

Please inform me about the serial number of your ACOM 1000.
You can replace the C5 3300uF 25V.
Should you have any further questions, I stay at your disposal.

Best regards,

Maya Georgieva
ACOM Export Manager

5005. A1010 blows fuse after heating up

Yahoo group: acom-list (2010 — 2016)
Date: 2012-08-01 10:22:45 UTC
From: lx1no
Topic: 5005 Message: 5005

Hi,

Before the recent IOTA contest took place, the A1010 caused a lot of headache. It's a fine amp that does the job it is designed for, but only if it manages to stay on after the 3min heat up period. Then, 4 out of 5 times, the 6.3A fuse is blown up.

The voltage in the shack is roughly around 250V, the A ist set for 240V inside.

Is there something like a current limiter that could be added or any other modification?

We finally decided to use an Emtron instead, which has no problem at all after the heat up problem.

Any idea/hint what to look for?

Hi Peter,

> I had exactly the same problem earlier this year ... it turned out
> to be a faulty GU7B tube.

I forwarded your hint. The tube will be removed and double checked again.

The fact is, that the amp was stress tested on true 240V into a dummy-load and it was all thumbs up. At the contest place with some 250V, it fails, often.

I'm nowhere nearby the amp, so can't check anything myself.

5008. ACOM 1000 Transformer failure

Yahoo group: acom-list (2010 — 2016)
Date: 2012-08-03 06:41:17 UTC
From: Steve
Topic: 5008 Message: 5008

After a couple of months of not being used I decided to turn on my spare ACOM and give it some exercise.
Unfortunately was greeted by error message PN07 which is HV fault related and the amp switches off. No bangs,no smoke,nothing inside overheated,distressed either in the RF compartment or on the circuit boards.
Very efficient tests carried out with Stan at Acom HQ and the diagnosos was HT transformer failure.
The LV side of the transformer was still OK.
Price for the HV transformer is 362 EUR, shipping costs to UK is 95 EUR.
Prices do not include VAT, 20%.
Thats a lot of money for something that has at most 200hrs of operation on it and of course being some 6 years old has no warranty.
Hope this is not becoming a common issue now.

Hi Steve

Please read : Message #4906

It seems for ACOM that a 6 or 7 years for a transformer life is quite normal !!!!!!!!

A big problem with this product for his fiability ! are you ready to spend 500 euros every 7 years ? I have lot of mail from other Ham with same problem.

Had two TL-922 since 25 years and never this kind of problem. Only replaced a pair of 3-500Z (normal use).

My dealer in France send my old transformer for inspection to ACOM 6 month ago ! no news .... I am waiting for the return of this one ! I want to keep it for a local expertise ...

I would agree it should be very unusual for a transformer to fail,if its not stressed (and mine certainly has not been).
I have old amateur valve rigs from the late 70s with HT transformers in that work 100%.Never an issue..
Same with broadcast transmitters at work-transformers generally work for the equipments lifetime when run 24hrs a day.30 year old spares are just gathering dust!
Its got to be a design flaw or manufacturing defect.

The only HV transformer that ever failed for me was one in a Collins 30L1 linear amp that had been running on 135 vac instead of 115-120 vac. After a few years, it finally failed probably because it was running too hot. I replaced the transformer and put a variac ahead of it to provide 115 vac, after which it never failed again.

FYI: I've reported, via email to Acom Bulgaria, in the past issues with the Acom transformers and their way of quality control this component. It was related to residual brown (looked like 'corroded coloured' substances left behind, hence not properly cleaned) before spray paint the transformers. This has been rectified immediately (better: instantly) as I have been confirmed by Acom Bulgaria and by checking myself in numerous new units afterwards.

Reading the responses, beside some random component failures (forgetting the early version caps and relays) that seems to happen to almost every manufacturer, this seems to be THE component that is the one to take extra investigations into for when buying an Acom 1000/1010/1011 second hand?

I would agree it should be very unusual for a transformer to fail,if its

not stressed (and mine certainly has not been).

I have old amateur valve rigs from the late 70s with HT transformers in

that work 100%.Never an issue..

Same with broadcast transmitters at work-transformers generally work for the equipments lifetime when run 24hrs a day.30 year old spares are just gathering dust!

Its got to be a design flaw or manufacturing defect.

Hi OM Peter,

See here my review:

http://www.eham.net/reviews/detail/1694?page=7

* - Transformer?s mounting base plate has brown colored
spots. These spots were noticed on both the units. The transformer is
welded on an Aluminum base plate while the transformers has metal pieces
and apparently not well enough cleaned & painted and/or protected.

I removed the transformers, sandpaper and cleaned the spots carefully
and prepared them with an anti rust layer and twice a layer with shiny
black metal paint. Looks like new now, but I did not like phenomenon
this at all.

Dated Feb 10, 2006. Review was sent over email to Acom for review a few days before publishing on eHam.

Honestly, I am feeling very sorry for the few HAMs with these transformer failures. On the other hand, with the very low numbers reported this has to be simply a matter of bad luck. I would like to advice Acom to help out the HAMs that suffer from these defects in a more less strict economical way. (Acom reads this forum closely, hopefully they want to take this advice in account).

Acom still produces the very best quality amps a HAM can buy against a reasonable price. In example, an average rating of 4.9/5

on eHam out of 124 reviews is what other manufactures only wish for!

Hi Morrie,

Not sure how relevant this will be to you, but the only time I have heard this type of noise and I would say noticeable rather than loud was when I ran power from a generator that wasn't an inverter type. I haven't used this type of generator since and I have had no problems. My Honda 65is has caused no problems at all.

The amp type Acom 1000 units suffer from resonating, most noticeable when you put your ear close to the top cover, right - back side and and TX with a carrier. The more RF output, the more hum will be noticeable. The "fix" is to put something in between the plastic cover inside the amp and the metal outside-cover of the amp. Acom provided me some stuffing material, which has a kinda glue on one side of the material and that side I pressed on the plastic part inside the amp. When attached, the hum is hardly noticeable anymore.

Yes.

All Acom amplifiers are compatible with all modern radios without any keying buffers or such devices.

Hi Morrie,

New units do hardly suffer from this phenomenon,. However, when the unit is in use lets say for a 1/2 year or so, the hum is more and more noticeable. The fix is easy, the solution I provided earlier :-) (IF this relates to what you describe of course)

Fellow ACOM users this is a reminder for you to check your filters and clean them. We easily forget to do that but in the heat of summer
and the dust [Arizona is dusty] will effect the performance of the amplifier.

SO....climb behind your amplifier and clean your filter to ensure maximum air flow and top notch operation!!!

I don't know if this is relevant to a GU74b pentode, but the classic symptom of many tubes is the output rolling off of output power on the higher frequencies when they are near end of life (a/k/a a soft tube.) If one or both of them are wearing out, that might be how they'd show the problem. Just a guess. If they have a lot of hours on them, it is even more likely.

5031. Low output 12 and 15 Meters

Yahoo group: acom-list (2010 — 2016)
Date: 2012-08-17 23:07:09 UTC
From: D G
Topic: 5025 Message: 5031

From my experience, also had this happen and was an early sign of a weak tube (or two). It was then followed by some Bias Voltage Low Eroor on the remote (pardon me, I am an Appliance Op).
The solution was a new pair of finals, although just one tube was bad (maybe one tube could have been replaced, but not matched pair, not sure if necessary...likely debate next on matched pair needed or not...).

Subject: [acom-list] Low output 12 and 15 Meters

Hello,

Have a 2000A. Output about 1 KW on 12 and 15M. All other bands seem ok, 1.5K out. Ant SWR good, checked with dummy load - OK.
Sent e-mail to Acom but no response ??

Any ideas on what to check ?

Thanks
Jerry, KE9I

Did you try the manual tune and not automatic. Each band has to be set up
and I have no idea how long you have been using the A2000 ACOM. Last
resort, on Monday, call Bob at Array Solutions.

Also, what is the plate current showing on these bands at 1 kw out?
If you haven't done the autotune on these 2 bands in each segment, do that
again.

What are the currents and voltages on these bands. How does it compare
to other full power bands.

Sounds like you got another antenna selected in the amp on these bands
and hence goofy tuning settings. Look and see if it is A0 or something
else.

Did you try retuning the segments?

With Tropical Storm Isaac in Florida, came power outages. My ACOM was on-line when the power went off. Several days later, when I tried to turn it on, I got the following message: BIAS TOO LOW AT POWER ON: -63V. The recommendations show: OFF5; CCC. I did that. I even unplugged the amp from the mains - still no joy. Any suggestions on how to proceed?

I have had a power failure with my amp on ,which caused the memory chip to go bad. It took out my call sign I was still able to get it power up. The Fix was to replace the chip in the control head . This fault your getting is common when a tube go's bad or theirs a problem on Low voltage side of the power supply . If you getting around 4000 hours or so you could have several thing that gone bad . Start by looking at the voltages on the tube .And check your line voltage . BY the way my Acom has over 10000 hours on it ,I also have the 1000 . Needless to say I believe that Acom makes a great product ,with the exception their antenna switches are not Very good .

There first generation switch has had issues with the relays staying closed resulting poor contact and not able to make more than a few years , the first couple years it was covered and repaired twice . Its slick package that should be non issue but after a few years the contacts start to drop out and receiver sensitivity goes away . I talked with someone at Dayton and had some great lip service on emails . But did really get resolution to repair the problem ,9 position switch got 4 left that still work . I been told the new switch is different . I thought it was pricey at 500.00 Now there over 800.00 Guess I Should bought DX engineering switch . Save your money the amp is great switch was disappointment . I had two of these bought just have one left and they both failed .

Mike,

It could be the bias supply is bad. Historically C2 on the LV PCB goes bad and the bias voltage drops which gives a Bias Too Low alarm. Voltage should be up around -120 to -132V.

If you feel comfortable testing the amp I can send you instructions from the factory on testing for the bias voltage. If you don't feel comfortable doing that, Array Solutions does a good job.

5047. ACOM 1010 - RTTY button does not limit

Yahoo group: acom-list (2010 — 2016)
Date: 2012-09-01 16:03:14 UTC
From: lledlow_jr
Topic: 5047 Message: 5047

All, I've been using my ACOM 1010 for a couple of years now for CW and SSB. Switched to RTTY this weekend and find the RTTY switch does not apparently limit output to 500W as I think the manual indicates it should. Any thoughts on this?

5048. No output, high bias

Yahoo group: acom-list (2010 — 2016)
Date: 2012-09-01 16:28:18 UTC
From: Hal Kennedy
Topic: 5047 Message: 5048

Before I open it up, wondering if anyone has a clue. One of my 2000As is acting up.

On start up a few days ago it threw a fault: "?? low bias." Can't remember the exact words. On the second try it started up and has been fine until this morning.

Now it has no output and the bias reads -127V without PTT (normal) and -105V with PTT pulled in (should be more like -57V). It band switches fine, but no ouput would be indicative of bias too high.

Both tubes were junk when they were installed 4 years ago. It could always be a tube, although it doesn't seem like it.

Hal:

IIRC, -105 V bias is the normal condition when AMP KEY is triggered, but no RF is present. An RF sensor then moves the bias to -57 when it sees a small amount of RF, thus keeping the plate current lower between syllables in phone or key down times in CW. I sounds like the RF is not being seen by the sensor circuit. Maybe a shorted grid would do that. What kind of plate current, grid current, screen current and input SWR do you see?

Have done some work. Replaced both tubes with known good ones and the amp is still sick. As it completes power up it faults off with "grid bias too low -XX volts."

I have seen XX as low as zero, but its usually around -25V.

Everything else looks normal. Screen voltage, plate current, filament voltage and currents all look okay. I need to go read the archives, but there is an electrolytic on the low voltage board that has failed on many of the early amps and this is an early one. Anyone know where I can get that cap? I think its rated around 325V.

Hal

Before I open it up, wondering if anyone has a clue. One of my 2000As is acting up.

On start up a few days ago it threw a fault: "?? low bias." Can't remember the exact words. On the second try it started up and has been fine until this morning.

Now it has no output and the bias reads -127V without PTT (normal) and -105V with PTT pulled in (should be more like -57V). It band switches fine, but no ouput would be indicative of bias too high.

Both tubes were junk when they were installed 4 years ago. It could always be a tube, although it doesn't seem like it.

I ran into the same low bias reading, and it turned out to be one of the little interlock switches on the chassis that was slightly out of adjustment. It looked like it was right, but was missing its closure by about 1/32". A quick bend fixed the problem. It's surprising there isn't an "interlock fault" indicator...instead it shows as low grid bias. It's a long shot, but worth checking!

The bias power supply cap is a good suspect. Keep in mind that the if the bias reads low, it could be because the bias is low, or that the sensor circuit thinks the bias is low and it's not. I bring this up because that also happened in my 2000A...it turned out to be a cold solder joint along the line that measures the bias voltage and signals the CPU. Also, check the bias measurement calibration pot which might be dirty.

Subject: RE: [acom-list] No output, high bias

Have done some work. Replaced both tubes with known good ones and the amp is still sick. As it completes power up it faults off with "grid bias too low -XX volts."

I have seen XX as low as zero, but its usually around -25V.

Everything else looks normal. Screen voltage, plate current, filament voltage and currents all look okay. I need to go read the archives, but there is an electrolytic on the low voltage board that has failed on many of the early amps and this is an early one. Anyone know where I can get that cap? I think its rated around 325V.

Hal:

IIRC, -105 V bias is the normal condition when AMP KEY is triggered, but no RF is present. An RF sensor then moves the bias to -57 when it sees a small amount of RF, thus keeping the plate current lower between syllables in phone or key down times in CW. I sounds like the RF is not being seen by the sensor circuit. Maybe a shorted grid would do that. What kind of plate current, grid current, screen current and input SWR do you see?

Mike,

It could be the bias supply is bad. Historically C2 on the LV PCB goes bad and the bias voltage drops which gives a Bias Too Low alarm. Voltage should be up around -120 to -132V.

If you feel comfortable testing the amp I can send you instructions from the factory on testing for the bias voltage. If you don't feel comfortable doing that, Array Solutions does a good job.

From: Hal Kennedy
Topic: 5038 Message: 5056

Currently working through this myself. I have a C2 cap and spares on order from Mouser - they will be here Monday and Ill see if that fixes it. After that, there is a varistor easily reached down at the tube sockets, that goes from the grids (in parallel) to ground. Those can get leaky or short. Mine is not shorted, but beyond that they are hard/easy to test. The easy way is to lift one end and turn on (but not operate) the Amp. If that's not it, then all the caps and zener diodes on the LV board will need to be checked. The LV supply doesn't have many parts..this is fixable.

Hi
I suggest to install the extra fan all the time, even if you do only SSB.
More is cooler , better it is.
I've installed a 12v computer fan, not expensive easy to do.
Just put or ask the extra fan when you buy the amp.
This should be installed by acom without being an option.
7 bars is around 70°c
here bars are nearly the temp i read in info.

Subject: [acom-list] Optional Fan

Is anyone using the optional fan? When doing RTTY contests, the amp gets very hot. Seems that the fan would help with cooling.

That's a gain of over 100 which is close to impossible, even with grid driven tetrodes and no cathode resistors. Time to check the wattmeters.

Bruce,

As others have said, that kind of gain is not possible. If you are using the Amplifier built in watt meter I would suspect some kind of failure in those circuits. I would use an external watt meter to verify the numbers.

Check SWR between transceiver and amplifier.

There is 50Ohms resistor on amplifier input.

If this resistor is bad you can have this output with small drive but
SWR between transceiver and Amplifier input will be HIGH

Steve,

Is the metering correct? I had a similar problem on my 1000 that caused it to trip because it thought the HT was too high. Ron's man eventually tracked it down to an A/D reference error on the processor board. If you can, check other readings, like the temperature and see if they're low, because a reference error will affect everything.

Good luck, 73 Bob

Bob unfortunately as the amp trips immediately upon pressing 'operate' its not possible to view metering such as HT.All I can view are the error numbers in the turned off state after the trip. Stan at Acom has come up with a suggested way forward injecting 24V ac into the rectifier chain and making measuremnts but Im thinking there may be an issue in the HT voltage divider chain on the rectifier board but have not had time to fully investigate what could be a leaky zener or capacitor.Will report back in due course.

Problem solved and with hindsight quite simple.
It was a leaky D6 (4.7V zener) on the HV sampling/rectifier board.This was dragging down the sample from the 3KV DC and causing the trip.
Faith in Acom 1000 transformers has been restored.......

I measured the swamping resistor by disconnecting the input coax and measuring the resistance across the input PL259 with the PTT shorted. It measured 50.1 ohms. The transceiver SWR is very low as well.

I sent a continuous tone to the amp while taking the power readings.

I verified the amp output with a LP100A external wattmeter as well as the LED display on the RCU. The interesting thing I have found so far is the RCU LED forward power display doesn't match the FWD-P reading In the measure mode of the RCU. The LED's and the external wattmeter match but the measured reading is about half of the other two.

Hal,
After you check the line voltage and see that it's with specs here is something else to look for.... Make sure the line voltage matches the RCU reading to be the same. If the line voltage is different and the RCU reads higher this can be adjusted by RP13 (line) on the board interface. A higher reading on the RCU will flash but will not hurt the amplifier. THANKS Guys, I was worried Something was amiss here..
For some reason we have had a bit of trouble with "DIRTY" Voltage in this area all of a sudden, so I'll check into that ASAP!..
I have Everything in the room on Battery Backups, except the AMP/Radio as they have way too much draw (IC-7700 200W).
THANKS again, and as long as there is nothing "Damage wise" I can try and get NH8S today..

The heater LED flashing provides information regarding two
parameters.

1. heater voltage problem...usually too high..intermittent flashing
2. 240VAC line voltage too high..LED flashes rapidly.

The ACOM 2000A heater voltage range is in your operating manual
under specifications..My 2000A typically is 13.2V-13.3V

Measure the 240VAC line voltage coming into your shack
DO NOT RELY upon what the RCU displays...mine was almost 5VAC off

Typical 240VAC line is +/- 5% -or- 228VAC low end 252VAC high end

Your local power company may boost your 240VAC line during times of high demand...
I strongly suggest you get an outboard line monitor.

If you determine the ACOM line voltage display is different than
your measurement you can adjust it.

At this time I forget the specific pot to adjust but it's on the
control board. That's the board behind the front panel.
A quick check of the schematic will direct you to the specific pot.

How many hours do you have on your tubes?

Martin;
THANKS for the Added information..
I'll look into some Outboard monitor, may have something at work.
As for Hours, well maybe 30/50hrs..
Got it at the end of last year, and the Summer here was (Lets say warm) for Michigan and the added HEAT in here wasn't needed. We have been having some Poor Power Condition here and think that was a BIG problem. I had it on Yesterday (Trying to get NH8S in the LOG) and saw Zero issues. As per your Note it would have been Heater Voltage as it was not flashing Rapidly, so may be worth a good look, and could most likely need a good Dusting just sitting all summer?..
THANKS..
Jeff-N8NOE

5089. Need to change 2000A for 220V mains

Yahoo group: acom-list (2010 — 2016)
Date: 2012-09-18 13:29:02 UTC
From: pp5ms@pp5ms.com
Topic: 5089 Message: 5089

I need to change the mains on one ACOM-2000A to 220 Volts operation. I see two 220 Volts configurations and would like to know the difference between these to positions.

Is one for single fase and the other for two fase mains?

Here I have a single fase 220 Volts (only one fase and the neutral)

Whitch configuration is the correct one for me?

Thank you for any help.

Marcus - PP5MS

5090. Acom 2000A Fault: DEFAULT CHECK VSWR PLEASE REMOVE DRIVE

Yahoo group: acom-list (2010 — 2016)
Date: 2012-09-22 19:36:16 UTC
From: Dave Hawes
Topic: 5090 Message: 5090

I was experiencing the "BIAS TOO LOW AT POWER ON -0.000V" error message when turning the amplifier on. I took the front panel off, measured the bias voltages, which looked good, so I replaced the tubes. The amplifier then completed the power on cycle.

While I had the front panel off (but before testing the replaced tubes), I preemtively replaced the vacuum relay, as I was getting a sporatic soft fault with error message indicating a problem with the vacuum relay. I have seen these before, and have replaced the relay several times.

Everything seems to work properly with the amplifier at this point, except one thing: I can't "AUTO TUNE." If I try, it seems to do the proper job, but then gives me a soft fault with the following error message:

DEFAULT CHECK VSWR
PLEASE REMOVE DRIVE

The amp's power meter is properly reading reflected and forward power, and I am getting decent output, but attempts to AUTO TUNE are unsuccessful.

Any ideas?

73 - Dave N3RD

Hi Dave,

The manual indicates that when you get the error message DEFAULT: CHECK VSWR it means that the auto tune can't find an acceptable match, either due to high VSWR or unstable drive power.

When troubleshooting, I always look to the latest problems and changes. You replaced the tubes because of a bias problem and you changed the relay. Those are the places I'd start.

A bad relay contact or maybe even bad wiring or soldering to the posts could cause the tubes to see high VSWR, but that seems unlikely because the amp works OK with previously stored tuning parameters and I assume you aren't seeing excessive or unexpected reflected power when you transmit at full power. Further, the wattmeter comes after the relay, so I don't think it would show high VSWR if the relay contacts were bad.

That leaves the bias problem. It's conceivable that there's something wrong with that circuit, and that replacing the tubes didn't really fix it. If you followed procedure and readjusted the bias when you changed the tubes, you may have simply changed the symptoms of the problem. It's possible that the bias voltage is now unstable at low drive levels, which in turn causes the output power to fluctuate and the auto tune to fail.

Just guessing here, but those are my thoughts. I have a feeling that an email to the factory will be your shortest path to a resolution.

Topic: 5090 Message: 5092

Hi Dick,

I took the lid off to inspect the soldering job on the relay, and as expected, it was satisfactory, which left the tubes. Hal, N4GG, informed me that he had a tube(s) that worked OK, but the amp would not AUTO TUNE, and it was fixed by replacement of the bad tube(s). I had another spare set of tubes, so I swapped them out, and the amplifier is now working properly.

This means to me that of the four tubes NOT in the amplifier, I have at least two bad tubes. One set was giving me the BIAS error, and the second set was giving me the AUTO TUNE problem. So, I have to take some time and swap one tube at a time to see if I can isolate the two bad ones.

It would be great if there were some facility here in the states that would test tubes for you. In the old days, if you were an Alpha owner, ETO would test your tubes for a nominal price. Does anybody know of a place that would test GU74Bs?

Thanks, Dick, for your suggestions.

Hi Dave,

Glad you got the amp working. Weird that the bad tube works for full output but not Auto Tune.

Where did you get your spare tubes? I got a set from Array Solutions, but they're sitting on the shelf.

I also experienced the same symptoms of no auto-tune. Once tubes replaced (purchased from Array Solutions), the amp behaved as new!
Glad to hear you got your amp going again DAve.

5095. Acom 2000A - IP=610ma Should be zero

Yahoo group: acom-list (2010 — 2016)
Date: 2012-09-27 10:40:27 UTC
From: N2TK, Tony
Topic: 5095 Message: 5095

Was listening for 3D2C on topband. Amp was sitting idle. Heard him and called. As soon as I called with 40W drive I got an alarm " IP=2550ma. Should be zero". Amp shutoff. When I try again I get an alarm after about 5 seconds - "IP=600ma. Should be zero".

Has anyone seen something like this? Not sure if a tube went or a bias supply. Will try to get time later today to pull the tubes and see what happens. Thought I would first check here for a shortcut.

Tnx

N2TK, Tony

Has anyone used the new video controller with the 2000A?
Any user reviews?

I also saw the ACOM website hinting a "new improved" 2000A
Does this simply mean they will include the video remote unit
with any NEW purchase instead of the original RCU?..or are they changing the 2000A design?

"Video remote" ? I think you're referring to the new controller with the color LCD type display. We showed a working prototype of this controller in Dayton this year. Very nice and integrates with most popular transceivers. As you tune the radio, the amplifier adjusts to be ready to go. No need to transmit for the amplifier to know where you are.

The amplifier is unchanged and will continue to ship with the original controller for some time - we don't know for how long.

The new controller will be an additional purchase option.

We anticipate that it will be around $900 for the new controller.

Eventually, the amplifier will be provided with the new controller only.

I have enjoyed my 2000A for about a year now. I remember asking Bob at Array Solutions at the time of purchase about the "new" RCU that Acom had announced for the 2000A. Well Bob, it has been about a year. Is the new RCU a reality of is it just more bleepin vapor wear?

Well, it has taken a while to get it right, but it's due to be shipping in
a couple of weeks.

As I said in my earlier message, we had a working unit in Dayton, and
based on that and our input, Acom is close to delivering now.

You can see it here:

http://www.arraysolutions.com/Acom/NEWRCU.htm

I attended the show in Germany the last couple of years. The unit is real for I saw it working at the Acom booth both years and understand ACOM would start shipping this October. Don't believe at this point I would spend the money to replace the RCU on my 2000A right away. Just would have to grow and love the new RCU more like seeing it here in the states. Bob will kept you informed as with other people also waiting...Joel, K2QBV

Hi All

I notice that to get full output I have to use more power from my rig than before, usually around 60w was enough to get up to 1kw,

Now I nearly have to run it at full power to get that, its worse on 10m

The RF power Gain is only showing 12.0dB I am sure it used to show more,

I don't use the amp that much and its about 5 years old,

would the tube be getting weak ???

Thanks

I had the same problem a year ago: gain dropped here to 11.5 dB on 20 meter and was different on other bands with max. 12 dB on 15. I installed a new tube and all OK since today: 12.5 - 13 dB gain depending on what band.I think your tube is not worn out but installing a "fresh" GU74 will likely restore the initial gain. Personally I should not worry to much as long as you get the full output.

5106. Acom 2000A "new RCU" controller

Yahoo group: acom-list (2010 — 2016)
Date: 2012-10-16 14:57:45 UTC
From: Kenneth
Topic: 5106 Message: 5106

I am missing something here. For current owners, where is the beef?
Yes its prettier. But I operate remotely and do not even see my RCU.
For $900 I can replace my finals, or buy a lifetime supply of Makers Mark.

Ken K5WK

5109. RCU Backup plan?

Yahoo group: acom-list (2010 — 2016)
Date: 2012-10-19 14:15:25 UTC
From: Ron N5QQ
Topic: 5109 Message: 5109

A recent failure of my RCU (that was immediately fixed by Array Solutions, thank Jay, Bob) caused me to think about a backup plan if another RCU failure occurred at an inopportune time.
Will any of the 3rd party ACOM software controllers, like Remote Rig, M0YOM's Director, TRX, etc be able to control the ACOM if you remove/disconnect completely the bad RCU? For the sake of this discussion don't worry about the power-on part, we will assume you are at your station and not operating remotely via the internet.
I don't have my ACOM set up for 3rd party software control so just haven't been able to field test it myself.
Anyone tried this? Or?
Ron

I know for sure they having some problems with the new RCU's colour display. Acom delayed the delivery of the first shipment already 3 times in a row according to my dealer. I ordered the Acom2000a with new RCU but Acom won't ship to the dealer network until they are satisfied. I'm getting worried. I hoped to have the amp on my bench for the upcoming CQWW but Acom emailed my dealer this week saying another delay will hold shipping until 25th of october. The amp will never get here in time. I'm waiting over 8 weeks now. If I had other options this week, I cancelled my order but options are rare. CQWW barefoot? No, thanks...

As from what I've been informed, the amplifier itself remains unchanged. Only some new functionality on the RCU and the new colour display is different.

Also the Acom 800s should be available around this time.

5111. Acom 2000A "new RCU" controller

Yahoo group: acom-list (2010 — 2016)
Date: 2012-10-20 03:20:04 UTC
From: D G
Topic: 5106 Message: 5111

The only possible issue I have heard is extremely minor, with the plastic antiglare screen, which has nothing to do with the operation of the ACOM 2000A or the new CAT RCU. I assume they will be testing new plastic screens and shipping very soon.

I am glad I returned to ACOM and bought another ACOM 2000A as well as the new ACOM 1500 which is working great on 6 meters, and I look forward to the ACOM 2000A CAT RTU.

From: Bob Naumann
Topic: 5106 Message: 5112

The new RCU is supposed to ship very soon. My understanding is that publishing the new manual is the only thing delaying shipment now.

There have never been any published or announced expected shipping dates, so there have been no (3 times in a row?) delays in delivery. All of this is just speculation by your dealer.

There is no reason not to use the original RCU with your amplifier. It's not like the amplifier is useless without the new RCU.

Originally, it was expected that the 2000A would continue to ship with the original RCU and that the new RCU would strictly be an option.

There has been a change in plans and that is that new 2000A amplifiers will begin shipping with the new RCU only very soon.

The development and perfecting of the new RCU has taken long enough that Acom has decided not to produce any more of the original RCU and the Acom warehouse stock level of the original RCU is depleted enough that they have made a change in plans.

The new RCU will still be available alone as an upgrade option to all existing 2000A owners, as originally reported. All of this will happen very soon.

Also, I have not heard anything from Acom regarding the 800S being available any time soon. I think this also may be pure speculation by your dealer - but time will tell.

The new RCU offers new capabilities in interfacing with your radio and for remote control. In addition, you can see much more data on the beautiful color screen at one time without pressing buttons and navigating menus as you have to on the original RCU. You are correct that the amplifier chassis is not changed whatsoever at this time. Eventually, the connection required by the original RCU may be removed, but at present there is no announced plan to make those changes. So, all new amplifiers will continue to work with either type RCU - original or the new color one.

Is upgrading worthwhile? Each 2000A owner will have to make his own decision.

5113. Re: [acom-list] Acom 1000 drive level and RF power Gain

Yahoo group: acom-list (2010 — 2016)
Date: 2012-10-20 11:19:52 UTC
From: Trevor Dunne
Topic: 5099 Message: 5113

Just to update this as I didn't get much response the first time around,

I did a test on all bands and they are all ok with the exception of 10m.

on 10m If I am running 50w with the amp in STBY the meter on the amp shows 50w as it should,

If I bring the amp on line, I am only seeing 40w drive when it should be 50w as I have not touched the drive level on the rig,

I checked all other bands and the difference between STBY PWR and Drive PWR when amp is in line is maybe 1 or 2w, not the 10w that is showing on 10m, I notice the SWR will rise a small bit as well, would the circuit in the amp be out of tune on 10m or maybe some sort of issues with the tuner/coax switch, patch cables???
 That's why I have to push the Rig harder to get the same output on 10m,

It's not a issue I am to concerned about bit will monitor it to make sure it does not get any worse.

Thanks
Trevor

Subject: [acom-list] Acom 1000 drive level and RF power Gain

Hi All

I notice that to get full output I have to use more power from my rig than before, usually around 60w was enough to get up to 1kw,

Now I nearly have to run it at full power to get that, its worse on 10m

The RF power Gain is only showing 12.0dB I am sure it used to show more,

I don't use the amp that much and its about 5 years old,

would the tube be getting weak ???

Thanks

wear?

I have enjoyed my 2000A for about a year now. I remember asking Bob at Array
Solutions at the time of purchase about the "new" RCU that Acom had
announced for the 2000A. Well Bob, it has been about a year. Is the new RCU
a reality of is it just more bleepin vapor wear?

Thanks for the update Bob, sounds fantastic.

When you think about it, the ACOM 2000A has about the most consistent and lengthy DNA and evolution towards perfection of any HF QRO amplifier around, over a decade. And these new features and enhancements make a great, proven, reliable HF amplifier platform even more innovative and unique (Remote Control Unit and CAT Tracking as well as Antenna Tuning Transformer are not widely available, but are standard with ACOM 2000A).

I also like my new ACOM 1500 assigned to 6 meters !

Congratulations and thanks to ACOM and Array Solutions !!!

From: D G
Topic: 5106 Message: 5116

Hey Wild Bill !

Even more, the ACOM 2000A is really like a solid-state amplifier appliance in flexibility and modern features, but with maximum reliability, durability and maintainability.

So what...just wait 180 seconds for warmup, no muss, no fuss, no fragility...just lotsa performance and features without the solid-state hassles (I've been there and done that one) !!!

Hey Wild Bill !

Even more, the ACOM 2000A is really like a solid-state amplifier appliance in flexibility and modern features, but with maximum reliability, durability and maintainability.

So what...just wait 180 seconds for warmup, no muss, no fuss, no fragility...just lotsa performance and features without the solid-state hassles (I've been there and done that one) !!!

Topic: 5118 Message: 5118

I have had an Acom 2000 at each of my two hamshacks - I go to AZ in the winter to an RV park.
Now this winter I am operating remotely from AZ, so I have an extra ACOM 2000.
I just cant bring myself to sell it. I may keep it as a backup for my other ACOM 2000 - which almost never needs a backup. Its like a member of the family. It seems kind of silly.

Don't Sell Her !!!

I sold my first ACOM 2000A to buy a solid-state 160-6 Meter 2 KW amplifier, and after a few months of ups-and-downs, broke-up with the Italian gal and am happily reunited with a new ACOM 2000A.

5120. ACOM 1000?

Yahoo group: acom-list (2010 — 2016)
Date: 2012-10-23 04:05:43 UTC
From: Doug Smith
Topic: 5120 Message: 5120

Hello,

What's the general consensus on the ACOM 1000? I see four of them currently 'for sale' on qth.com with prices ranging from $2300 to about $2650. New units aren't much more at $3,250.

Good amps? How long have they been in production? If I was to buy a used unit what sort of questions should I be asking? Hours on tube, year built, etc. etc.

For a used to new price differential of ~600 ~700 bucks it might make sense to buy one new. Peace of mind has some value..

Anyway, anyone have any thoughts or advice they'd like to share?

Thanks and 73,
Doug, W7KF

From: on4vp
Topic: 5121 Message: 5121

Hello,

With interest I see that you have the Acom2000a connected to the Microham station master. I have the station master here in my station and the Acom2000 is coming in two weeks (on order).

My question:

I see the cable (have it already here) has a big connecter for the station master and a second thin cable for RS232.

I assume the big thick cable is for PTT keying and the RS232 cable connects to station master RS232 port and Acom RS232 port.

I don't understand what the grey plastic RS232 box is with blue cable marked "remote". According to the schematics I think it is for remote "switch on/off" ? Do I need to put that plastic RS232 box between RS232 cable and Acom?

Perhaps you could be so kind to send me a few pictures with the cables connected to view the situation.

Thanks for sharing info and best 73

I have seen this protect light blink many times and not worry about it.
I have the amp wired for 240 volts.
Now, sometimes I see the light blink constantly. It has put the amp in standby a couple of times. With the light constantly blinking, I can power down and back up immediately -- the light disappears.

Any ideas what may be the cause of this?

The yellow LED protect light has two functions:

1. to alert you that the tube heater voltage is high. The yellow
protect LED will come on and flash intermittently.

2. Your line voltage is too high likely above about 245VAC and the yellow LED will flash rapidly....

So...check your 2000A parameters and let us know what your
heater voltage and AC line voltages are.

Also I'd strongly suggest you use a digital voltmeter and measure
your 240VAC line voltage going to the 2000A. I found on my 2000A
the RCU line voltage display was over 5VAC off and had to calibrate the 2000A metering display.

Finally be aware typically 240VAC is +/5% or about 228VAC to 252VAC
That's why you need to measure your 240VAC source to determine if you need to call your power company. At times the line voltage may increase due to local demand..or there may be a problem at your
distribution point.

In the case of High Mains voltage being a problem from your power pole transformer.
I would ask to have it lowered.

...But ACOM has a RCU fix to keep the tubes in good order and efficiency. Read the manual section 5-6 about telling the RCU you have High, or Low mains. Once set the firmware will adjust the tube parameters to keep it on a good load line. You must go through a new USER TUNE cycle on all your antennas to take advantage of this.

Regards to the group.

This is the RED led. I think I found the problem, and it does not seem to follow the script. If the voltage were high, I would expect the light to reignite when I turn the amp back on.

My Steppir antenna needed to be calibrated. I think the tuning of the amp was not agreeing with the antenna characteristics. I recalibrated, then retuned the ACOM on all bands, and I have not seen the flashing red light since. Perhaps coincidence?

Ken,

The PROT red led lights only in case of a protection trip. Please read the
fault description on the RCU display.
You may have a hot switching if the amplifier's keying line is interrupted
by the steppir controller.

While operating on 10 meter SSB at 1 kw the amp shut down and the red Prot light (top left) came on and stayed on. I shut the unit down waited 5 min and turned it back on. it came up OK and operated for about 20 seconds before shutting down again.

I restarted the unit and after the normal warm up waiting period the unit tried to start up and shut down in about two seconds and left the message that the "start up bias is too low -000 volts".

It now does the same on every attempt to run it. The key in line is operating as it should (open on receive and shorted during transmission).

Any help appreciated. Van W4GIW a ham for 59 years.

Van,

It sound like a bad tube, but the bias circuit malfunction is also possible.
If you have a spare pair, you can check whether it will make the amplifier
happy. If this is the case, don't forget finally to adjust the bias
according to the new pair needs.

Val, Thanks for your response. I have never replaced a ceramic tube but I do have a set of never used 7 pin russian tubes marked OTK 10 and ry-7469104 which are supposed to be the same as 4cx800a. Can you confirm that the tubes I have are equal. The tubes are several years old and have never been used. I know there is a special procedure to follow with old tubes but I do not know it. Can you supply a copy of this process.

Thanks for your help. Van

Should these solve your problem, make sure you adjust the bias pots
located under the front panel.

Hello to the group,
I wonder if anyone has had the problem with a ACOM 1000 tripping out with alarm TR6B.

No problems up till now.

It will work if reset but trips again after a while of use.

Any info would be greatly received.

73 to all.

Hi,

I have an Acom 1000 for sale. Has never left my shack.
Tube is fine, not that many hours on the clock. Only been used during my
time off in the weekends.
Only reason is Acom2000a + SPE (both auto) that I plan to keep.
Price 1500 euros. For those not to far away, can be checked and tested at
my place.
Can be shipped (extra costs).

Yes Van, the tubes that you have are of the right type. However are they a matched pair or not?

The only thing that you can do for the aged tubes is to bake them. Apply only the filament voltage for several (8-12) hours. This could be done in the amplifier if the plate voltage is previously disconnected.

5140. Super Gain 2000A - end of story

Yahoo group: acom-list (2010 — 2016)
Date: 2012-10-29 22:24:01 UTC
From: Jay Terleski
Topic: 5140 Message: 5140

You may recall Bruce had posted a quest for help for his 2000A which was giving him Full output with 12W input.

When I got the amp it was indeed showing 18.5dB of gain!

And the most obvious thing to check was the input swamping 50 ohm resistor as several of you suggested.

This was OK and putting an Ohm meter into the RF in port showed a perfect 50 ohms when PTT was pulled.

After making alot of measurements with a scope and with the help of ACOM (VAL and STAN) and a good Oscilloscope we tracked it down.
The RF output was 1000W with 10W input but it was peak power, the envelope was modulated by huge ripple on the bias supply. Even thought the bias supply said it was -127 volts at idle.
This was the strange thing about this whole problem. The ripple was on the DC component of the bias supply. So watch out for this.

C2 47uF 200V cap was blown open on the Low Voltage board.
Since this was a 1999 amplifier it finally dried out.

While in there I replaced all the other electrolytics, since it is a fairly big job to dig down to that board.

If you have a 10 year old amp you might want to replace the older electrolytics just to avoid missing the P5.

Regards to the group.

Van,

I recently had this exact problem. I first checked the bias level with a DVM on the appropriate pins with the front panel removed, without starting the amp with the red ON OFF button on the RCU. Perfect. Then while watching the bias, I started the amp, and just as it was about to finish the warm up cycle, the bias went haywire. This is a sign of a bad tube or tubes. Changed to a spare set, and all went well.

That is until I tried to use the Auto Tune function. It kept giving me an error, so I swapped in yet a third set of tubes, and now all is well with the amp.

So, I'd bet you have at least one bad tube.

My thanks to all who responded. The problem has been fixed. To those of you who suggested a tube problem you get the cigar. I chose one of the two tubes and replaced it. It was a lucky choice as it was the bad one. Replacing the tube was much easier than the manual would lead you to believe.

Thanks to Jay at Array Solutions for his fine telephone support. The bias was adjusted after replacement. Per Jays instructions, the new tube was allowed to only warm up for two minutes after the normal start up delay, before power was applied at 400 watts. We ran this for a min. or so and then went to 1400 with no problem. The replacement tube had been setting on the shelf unused for at least 5 years. 12 hours later an hour of regular operation at 1200 watts produced only normal results.

I hope these results may inable another owner to solve a tube problemin the future.

If you haven't already done so, you should compare the temperatures of the two tubes after a period of intensive use. A small temperature difference will verify that you have an acceptable match.

I'm curious why the NOS tube was only warmed up for 2 mins and then ramped up to high power in a relatively quick fashion. I would have thought to bring it up over several hours.

Great that you are going again! Out of curiosity, how old is the amp and the tube(s) that went bad?

to bake them....

just disconnect the plates and let them hang ???
this does not cause a fault ???

looking at two sets of "matched" spares...

thinking about swapping a pair into currently working fine 5 year old amp....
or should I just let them set awaiting a failure that may never happen/////

bill

5147. New 2000A - What to look out for

Hello all! After a lot of research and many discussions with other hams I finally did the deed and bought a new 2000A from Array Solutions. The brown truck just dropped it off. This is going to swap out an AL-1500 that I've been running for the past couple of years. Anything I need to look out for or things I need to be aware of or other words of wisdom as I get ready to put the 2000A into service?

Thanks
Rick - ND4P

Just pop the transformer in, re-install all the cabinet screws, and enjoy it.

The front power switch is upside down from American standards. Down is on, up is off...like in EU. Also, the fan is so quiet, you won't know it's on. You'll love the amp!

Well, it will put out more than 1500 watts. (But so would the AL-1500!) Be sure to hook up the ALC . . . :-)

Congratulations on your choice. I have the PW-1, ACOM 2000A, Alpha 9500, and Alpha 77Sx - the ACOM is my favorite "go-to" amp. It's the quietist amp and full power and band change is a dit away. Read pages 16-17 about USR-tunings. Easy to do.

Whenever I purchased a used sb220, I would get a broomstick, stand back about 4 feet and "punch it on". If it didnt explode on initial start, I was almost comfortable sitting near it in the shack. Never had that problem with my 2000a hihi.
Enjoy your new toy! Paul w8jn

This seems to be a common mode of failure for these tubes - grid bias issues. I have had a pair fail at around 6K hours, which doesn't seem like many hours to me. Had one fail after about 2k hours.

Just curious if the issue is the design of the tube, sensitivity of grid leakage by the amp, or I am just expecting too much out of these tubes?

Overall I am quite pleased with my 2000A for many years. And the support from Array Solutions and Acom has always been first class.

Too bad there wasn't a way to add 6M J

My thanks to all who responded. The problem has been fixed. To those of you who suggested a tube problem you get the cigar. I chose one of the two tubes and replaced it. It was a lucky choice as it was the bad one. Replacing the tube was much easier than the manual would lead you to believe.

Thanks to Jay at Array Solutions for his fine telephone support. The bias was adjusted after replacement. Per Jays instructions, the new tube was allowed to only warm up for two minutes after the normal start up delay, before power was applied at 400 watts. We ran this for a min. or so and then went to 1400 with no problem. The replacement tube had been setting on the shelf unused for at least 5 years. 12 hours later an hour of regular operation at 1200 watts produced only normal results.

I hope these results may inable another owner to solve a tube problemin the future.

5155. low bias warning on 2000A SN #060187

Topic: 5132 Message: 5155

That's what I did, both are quite sweet and like having the 1500 as HF backup to the 2000A, which is an advantage over monoband Alpha 6 meter amp which I onced owned while delivering about the same power.

But I do wish the ACOM 2000A final tubes lasted longer, some I have heard gone at 4000 hours, even while mostly in standby mode.

Tony - you just need to add an Acom 1500 to handle 6m for you!

Topic: 5132 Message: 5156

Dennis,

Most of the tubes do last a lot longer than that.

The more common experience is for no trouble at all. My amp is now 13 years old, with the original tubes, and has been in virtually every contest since it was new, and it's been to Antigua 3 times in addition to being at multi-ops here in the USA.

These things are very rugged and I suspect many tubes outlast their owners.

Hi Bob, that is AWESOME.
However, I lost one tube after 4000+ hours and 2 years however, mostly standby mode.
Hoping for better this time around.

73,

Dennis

From: wade
Topic: 5132 Message: 5158

IN answer to those that had questions.

The tube that went bad had 2500 hours and was the original and was 6 to 7 years old. The amp was built in 2006

The fast start up was based on the advice of Jay at Array Solutions. His position is that these tubes rarely ever have a gas problem even when the tube is old and has been sitting on the shelf for years. There is no need to to warm them up for hours as is often recomended. IN this case it appears he is correct.

Thanks for the tip on looking at the tube temp to see if the tubes are significantly different. Obviously they were not matched.

Van W4GIW

Per Jays instructions, the new tube was allowed to only warm up for two minutes after the normal start up delay, before power was applied at 400 watts. We ran this for a min. or so and then went to 1400 with no problem. The replacement tube had been setting on the shelf unused for at least 5 years. 12 hours later an hour of regular operation at 1200 watts produced only normal results.

I have a comment to as the statement "IN this case it appears he is correct. " This can only maybe be said after many years of trouble free usage of this tube! For now I would say "Not the most ideal procedure, if not the one that should be avoided".

Unless this was an already pre-warmed tube, I would NEVER ever recommend to simply drop-in a NOS tube without pre-heating (and thus activating) the getter material and a proper check afterwards on internal shorts.

IN answer to those that had questions.

The tube that went bad had 2500 hours and was the original and was 6 to 7 years old. The amp was built in 2006

The fast start up was based on the advice of Jay at Array Solutions. His position is that these tubes rarely ever have a gas problem even when the tube is old and has been sitting on the shelf for years. There is no need to to warm them up for hours as is often recomended. IN this case it appears he is correct.

Thanks for the tip on looking at the tube temp to see if the tubes are significantly different. Obviously they were not matched.

> >

> > Thanks to Jay at Array Solutions for his fine telephone support. The bias was adjusted after replacement. Per Jays instructions, the new tube was allowed to only warm up for two minutes after the normal start up delay, before power was applied at 400 watts. We ran this for a min. or so and then went to 1400 with no problem. The replacement tube had been setting on the shelf unused for at least 5 years. 12 hours later an hour of regular operation at 1200 watts produced only normal results.

Yep, I am with Kees, as usual, on this one. These tubes (unless defective) do not leak outside air into their vacuum. But, the getter inside the tube will out-gas to some degree if not heated for a period of years. The ACOM2000 uses a low enough plate voltage that you can probably get away with just popping a NOS tube in and firing it up. But a more cautious approach, and a necessary approach if you are using these tubes elsewhere near their maximum ratings, is to bake them with the filament on and HV off for some number of hours. Most US made tubes use "fired" getters, which are burned inside the envelop at manufacture and in so doing use up any remaining oxygen. Most getters in Russian tubes are more like a desiccant. They bind up oxygen when warmed up and will retain that oxygen for months or years, but not forever. Restoring the best possible vacuum just requires heating them up again.

My tube life here is running around 3000 hours. I asked Tom (sk), of Tom's Tubes once what he was seeing. His answer was 3000 hours. I suspect the distribution is very wide and someone could easily wind up with an 8000 hour tube. Or a 2000 hour tube. There is also known lot-dependence on GU-74bs.

This weekend I rotated a pair of new 8877s into my Alpha 77sx. Since it was easy to disconnect the HV I let the tubes warm up for several hours. I used a IR heat gun to watch the tube temperatures. Over about 3 hours the rise in temperature was only 7 degrees. Of course the blower was on and pumping lots of air through the tubes, the silicon sleeves were not on the tubes so the air was unimpeded. Based on what I saw would it have been better to put the tubes in an oven at the lowest temp and warm them to activate the getter material than trying to use the amp?

Once the amp was back together I used 10 watts of drive, the low voltage setting and short CW sessions to put heat into the tubes. This process worked well. Most of the information on gettering seems antidotal anyone have definitive recommendations?

Here some information about tube life: had to replace the tubes of my ACOM2000 after 29'000 hours of permanent 24/24 operation in a remote station, had also BIAS errors, low gain etc. Bought my tubes from vinecom, UK, Ron is a nice and helpful guy, affordable price and good matched tubes with measured and documented values, all your questions about pricing, delivery etc. are answered within minutes. Delivery to Switzerland took 8 days only. Change was easy, just follow the instructions in this forum. The amp delivers an output for 1.5 kw to the dummy load when driving it with 35 watts. A friend of mine had to change tubes after 9000 hours of operation in another remote.

5163. Acom2000a first time use.

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-03 04:55:44 UTC
From: Philippe ON4VP
Topic: 5163 Message: 5163

Hi group,

Just got word that my amplifier is on transport so it won't be long until I receive the Acom2000a.
It will be shipped with the new RCU.

I've been reading the (old) manual and found most things easy to understand. I own a Acom1000 to.
My guess there will be some changes regarding the new RCU but my most important question is what to do after installing the transformer.

I have 3 antennas.

1: Optibeam 5 band yagi, single feedline -> n°1 on coax switch (bands 10-12-15-17-20)
2: Dipole for 2 bands, single feedline -> n°2 on coax switch (bands 40-80)
3: Dipole for 1 band, single feedline -> n° 3 on coax switch (band 30)

Now I will run the amp from the microham station master, I have the special Acom2000a cable delivered.
The cable comes in two parts, one for the PA port to the Key in and Key out and one part for RS232

The station master manual explains that when first used, I need to tune all my antennas for all the bands they will be used on.
I have to assign a sequel number to the antenna so the station master can command the Acom2000a to tune the antenna from memory before I even transmit.

So how do I best proceed, just install transformer, switch on, and start with antenna 1, 2, 3 ... and tune all bands (segments).
For example, I start setting for 10 meters, select antenna 1 on the RCU and start from 28.000 and go up from there to 29.700, switch to 12 meters and do the same for all 5 bands... go to 2nd antenna and select antenna 2 on RCU, etc...

I hope I've filtered out the correct information. For those I want to check my findings, you can look at page 28 (serial functions) in the station masters manual : http://www.microham.com/Downloads/SM_English_Manual.pdf

Thanks for any advise.
73 Phil.

Hi Philippe,
I don't have the new RCU .
Regardless, I would take a step by step approach.
1)Use the ACOM stand alone without the microham station master. That is to say tune all segments for each antenna on each band.
2)Once you have done 1) and operated some then fool around with station master. There are likely some setup glitches both software and hardware.

While nice to have the amp "pretuned", it isn't necessary for operation as long as the correct antenna is present. The ACOM senses frequency and sets its segment tunings before a first syllable or dit is complete.

Hello all,
I just bought an used ACOM 1000 last month and I was waiting for my relay cable for the entire month to turn my PA on.
I saw the old owner showing me that was working, tuning on all bands with a max 1.2kw.
Long story short, I turned my Amplifier on and didn't work, right during the warmup I've got a message about SB26. So I checked the voltage and saw that was set to 240v and here it is 220v, I changed as show in the manual and did't work again. any thoughts?

Here are the messages from the first time to now

1ASB26 000000 000006
1BB298 0320DC D77FFB
2ASB26 000000 000006
2BB197 0720DC D77FF3
3ASB26 000000 000006
3BA699 0320DC D77FEE
4ASB26 000000 000006
4BA69A 0720DC D77FE9
5ASB26 000000 000006
5BA69A 0320DC D77FED
6ASB26 000000 000006
6BA69A 0720DC D77FE9
7ASB26 000000 000006

I'm not sure why Microham is telling you that you have to tune the amplifier for your antennas.

The Acom 2000A has default tunings for every band that you can use without trouble unless your SWR is very bad. And, if so, you only need to tune the amplifier where the SWR is bad.

I think you are making this much more complicated than it needs to be.

I would connect the amplifier without the station master and get familiar with the amplifier.

You may find that the station master adds nothing aside from complexity to your station.

Subject: [acom-list] Acom2000a first time use.

Hi group,

Just got word that my amplifier is on transport so it won't be long until I receive the Acom2000a.
It will be shipped with the new RCU.

I've been reading the (old) manual and found most things easy to understand. I own a Acom1000 to.
My guess there will be some changes regarding the new RCU but my most important question is what to do after installing the transformer.

I have 3 antennas.

1: Optibeam 5 band yagi, single feedline -> n°1 on coax switch (bands 10-12-15-17-20)
2: Dipole for 2 bands, single feedline -> n°2 on coax switch (bands 40-80)
3: Dipole for 1 band, single feedline -> n° 3 on coax switch (band 30)

Now I will run the amp from the microham station master, I have the special Acom2000a cable delivered.

The cable comes in two parts, one for the PA port to the Key in and Key out and one part for RS232

The station master manual explains that when first used, I need to tune all my antennas for all the bands they will be used on.
I have to assign a sequel number to the antenna so the station master can command the Acom2000a to tune the antenna from memory before I even transmit.

So how do I best proceed, just install transformer, switch on, and start with antenna 1, 2, 3 ... and tune all bands (segments).
For example, I start setting for 10 meters, select antenna 1 on the RCU and start from 28.000 and go up from there to 29.700, switch to 12 meters and do the same for all 5 bands... go to 2nd antenna and select antenna 2 on RCU, etc...

I hope I've filtered out the correct information. For those I want to check my findings, you can look at page 28 (serial functions) in the station masters manual : http://www.microham.com/Downloads/SM_English_Manual.pdf

Thanks for any advise.
73 Phil.

Also, depending upon your type of operating, having the ACOM2000 retune
as you tune your RX across the tuning segment boundaries will add noise
from and duty cycle to the tuning gizmos. They are noisy. It makes
more sense to me to not retune until you have to transmit. One dit and
it's tuned.

I'm personally a KISS person and agree with Bob on not adding complexity.

I don't agree with Bob that retuning (once/segment) is generally
unnecessary. I don't live in Bob's world were all antennas are
perfectly matched-- especially when going from low CW to high SSB freqs.
You do this only once unless you change antennas. Why not do it for
all segments.

Brian,

My concern is the "have to" that is being associated with the user tunings. It is totally optional to do this, and recommended in cases of poor SWR.

There is no requirement that you have to use the feature that allows for user tunings. You certainly can, and if you feel it's necessary, by all means go ahead.

The point is that with most antennas (like Phil's OptiBeam) that have a good SWR, you just don't need to do it.

Regarding the retuning, the way the new RCU works is precisely as you have described.
That is, (if you have your radio interfaced) as you turn the dial, or change bands, the motors in the 2000A will move and have the amp pre-adjusted for you without you needing to give the amp any RF to detect where it should go.

There are two schools of thought on this:
1: the new Acom approach is the keep the amp tuned as you move your radio around; and
2: the new OM Power amplifiers will stay with you as long as you don't change bands - upon a band change, the OM Power amp requires you to do a PTT operation to "confirm" that you have changed bands and it needs to retune there.

I understand both, and I'm not sure which is better.

As far as the noise goes, retuning within a band makes very little noise as the bandswitch is not actuated and the cap motors turn very little. Going to another band is a bit more noisy as the band switch operates and the caps can turn a lot. As you might imagine, going to an adjacent band is less noisy than going from 160 to 10m for example.

I think the original, RF Sense band change method is still very good and the fully automatic features that will be present in the new RCU are not necessarily a panacea.
I suspect that many users will not interface their radios and continue to use the proven RF sense method as it is indeed simpler.

73,

Bob W5OV

We have had software in the contest station here that would pre-tune the amp before transmitting as it was switched amongst antennas, bands and band segments by computer control. When its all setup and working properly, I think it makes contest operation smoother.

Regarding the need for tuning each segment, our experience is that, while the amp is very tolerant of imperfect tuning, things do get better when custom tuning has been performed. It's much easier to stay away from tuning-related tripping of the protection threshold if things have been pre-tweaked. Tuning also tends to ensure that you get relatively constant output from the amp for the same drive level as you switch amongst antennas and frequencies.

It really isn't fun to click on a spot, wait for the perfect moment to call into the pile, and then your amp trips out. It also doesn't feel great to arrive on the DX QRG and send a few dits to make sure you're tuned . . .

All that said, I totally agree with Bob that the place to start is with the standard configs - leaving the Station Master out initially - and learn how the amp works and how it behaves in your station, with your antennas. Then proceed to make decisions about what tuning is required, and finally add the Station Master to complete the solution with the pre-tune feature.

SB26. This indicates plate current during standby. The Acom 1000
signals spreadsheet decodes this to 30mA. However, the spreadsheet does
take a bit of interpreting.

It would be useful if this could be put in the files area. With a few
example protection code decodes.

Regards,

Mike VP8NO

I don't own the Acom 2000 (yet) but I do use the Station Master with a number of antennas and bandpass filters.

First I agree with Bob - use the amp first, get familiar with it, then integrate it into the station.

Station Master practically has endless possibilities and I think you need to integrate it step by step.

I do believe it is however critical to establish your the PTT and possibly your PTT out using SM as this assures that there is no hot switching and that the time it takes for your switch to change bands is taken into consideration. Hot-switching may not be the correct technical term actually but essentially operating into your antenna moments before the relay closes. This is especially important if you're planning on QSK.

SM is a pretty complex piece of equipment as is the A2000 so you need to be sure you understand fully itsoperational parameters before hook-up. If in doubt I think a query on the uHam list or to their support would be in order.

Thanks for all the extra info.

I think I agree to first get to know the amp and how it performs using it own rf sensing tuning.
If I continue to do that while learning the way the amp works on all my antennas, the amp will be pre-tuned for all bands on all my 3 antennas.

It is not the Station Master, imho, that makes it more complicated. If I want I just can wire the PA out to the key in and I'm done.

But I agree with Jim. Once I will interface the Station Master with the serial cable, my system will preset the Acom2000 when moving bands or switching antennas. The best part is that with all the features in dx spots in logging software, the amp will be set for the correct frequency when I click a spot or dx.

The Station Master works FB with my SPE Expert right now. It does about the same. Besides that, the Station Master also rotates my yagi and switch my coax relay for antennas. It is a box that provides automation to amplifiers, rotators and band masters.

The only thing to keep in mind is to carefully read manuals and set it up in a decent way. After that it is a joy to run a station that is controlled just the way you set it up so you can concentrate on working dx without trouble. To me it makes a big difference and it kept me away from making mistakes in the heat of the battle.

73 Phil.

5174. Acom 1000 Recieve problem

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-04 16:46:55 UTC
From: Tim
Topic: 5174 Message: 5174

Hi All
Looking for some help and advice from those that know (hopefully)
I have an Acom 1000 that transmits full power etc.
My problem is when i press the OPER button to turn on the amp it attenuates the received signal from the radio.
I am thinking that it is possibly a sticking relay?
I have had this problem before a couple of times and cannot remember what i was told to do to resolve the problem
If there are any solutions i would greatly appreciate any input.
Thanks
Tim

I can't tell since I'm not aware of prices before. I just put down the order 4 weeks ago and have been informed that the delivery will take place this week.

Hi Kees
Yes I run a Icom 756 pro 3
Thanks for your interest
Is there a procedure to reset the Acom do you know?

Hi Tim,

I was asking because Icom radio's suffer from a bad ALC design and produce a full power spike during the TX/RX and RX/TX cycle. Caused likely your relays problem. I have seen and repaired this phenomenon before for fellow HAMs, whereof 95% was owner of an Icom rig. I would recommend to replace the Acom RX/TX relays, most likely the problem.

Hi Kees
Thanks for the info regarding the Icom. I did not have any knowledge of this problem.
I will get in contact with the Acom engineer over here who does the repairs for Acom amps.
If anyone else has any comments they would be appreciated.
73 Kees and thanks again
Tim

That is certainly true of the older IC-706 radios and perhaps some others, but I'm fairly sure the 756 line don't have such an ALC excursion.

In the case of the original IC-756 which I use there is definitely no power spike. The power control, is very precise and well behaved.

73
Bill.

Tim,

Check first the control cable from the transceiver to the amplifier. Most probably it's shorted.

A buddy, who shall remain nameless, had the same RX dropout problem when he plugged his KX-3 amp line into the ACOM-1000

In his case it was the 2.5mm stereo plug on the KX3 end. The plastic housing overlapped the plug so it could not be fully inserted! Partial insertion shorted the ACOM key line to ground.

Trimming away the extra plastic solved the problem.

Beware of tiny plugs!

Hi Guys
I was a it technician and was all ways taught to trouble shoot by stepping back in recent events.
Guess what. Today i polished and dusted the shack. I think i may have disturbed the 2.5mm plug. Checked it out. Unplugged and replugged and away it went. Working Ok.
Thanks for all the comments and support. It was much appreciated.
Thanks to you Brian for making me stop and think. Sometimes you just cant see the wood for the trees.
73 and thanks again Tim

Do not forget to clean the contacts of that 2.5 plug with some alcohol and a clean cloth before re-inserting.

Hi Guys

I was a it technician and was all ways taught to trouble shoot by stepping back in recent events.

Guess what. Today i polished and dusted the shack. I think i may have disturbed the 2.5mm plug. Checked it out. Unplugged and replugged and away it went. Working Ok.

Thanks for all the comments and support. It was much appreciated.

Thanks to you Brian for making me stop and think. Sometimes you just cant see the wood for the trees.

73 and thanks again Tim

5185. Acom 1000 - Auto Or No Auto

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-06 12:23:32 UTC
From: Bubba
Topic: 5185 Message: 5185

Just got me new Acom 1000 and set it up and all working just great.
Love the ease of tuning.

My question is using the Auto Operate or not?

I had one back a 5 years ago and don't ever remember using the Auto
Mode. Anyone have any preferences?

Thanks.

Steve

Hi Steve,

I've always used my '1000 in Auto mode. The only problem I've had is down to me causing the very occasional hot switch as the warm up timer zeros whilst transmitting. Normally not a problem, if I'm in that situation I keep an eye on the count down and drop the PTT just before zero and back off the drive. Sometimes you have to go for it before the amp comes on line!

Regards,

Mike VP8NO

5190. setting AC line voltage

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-06 17:41:28 UTC
From: Philippe ON4VP
Topic: 5190 Message: 5190

As I told in a previous message my new acom2000a will be delivered in the nex few days.
I've been informed that my transformer is set for 220VAC but when I check the house voltage I see 232VAC so I think it is safer to set it for 240VAC.

1/ Would it be best to set for 240VAC instead of 220VAC?
2/ I can't find info in the manual (downloaded from acom website, is it hard to do? Where do I change the input voltage?

Thanks, Phil.

From: W5OV@w5ov.com
Topic: 5190 Message: 5191

If your AC power in your area is supposed to be 220v, you should have your amplifier set to 220v. It can operate with at least +/- 10% or from 198 to 242. So if you're in that range, leave it that way.

The line input jumper positions in the 2000A are detailed on the schematic page in the manual. There is a graphic on the schematic showing the various positions of the metal pieces for the various line voltages.

5195. ACOM HF Antenna Tuner ???

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-06 18:06:11 UTC
From: D G
Topic: 5190 Message: 5195

I love my ACOM 2000A and ACOM 1500 Amplifiers and looking forward to the new CAT Remote Control Unit.
ACOM Build-Quality is Excellent indeed !

As much as the ACOM 2000A is tolerant on SWR <3:1 with her matching transformer, I'd like to protect her at band edges particularly on 160 & 80 meters. I have a pending order for the new Alpha 4040 Automatic Antenna Tuner to replace my Palstar AT AUTO and was wondering if ACOM (or perhaps OM Power) may be planning anything or in the works in near future ?

Thanks and 73,

Dennis
N3DG

From: ea3ku@arrl.net
Topic: 5174 Message: 5198

Hi Gerald,
I read carefully the answers to your question. I am glad you solved the problem.
Anyway, it is generally true that ICOM rigs not get along very well with the ACOM 1000. For everything I have read is true that the start transmitting generate a "spike" of power.
I have also an IC-756 ICOM PROIII among other ICOM equipment. It is good practice when activating any linear amplifier, not just an ACOM 1000, ensure that the relays do the switching linear cold. That is achieved by introducing a time delay circuit in the transmission between the activation of the power amplifier and the transmitter. This will always relays switching work in cold and without power and your life will be much more durable. This advice is very important for the older linear amplifiers where the switching time of their relays may be slower.

Hi Gerald,
I read carefully the answers to your question. I am glad you solved the problem.
Anyway, it is generally true that ICOM rigs not get along very well with the ACOM 1000. For everything I have read is true that the start transmitting generate a "spike" of power.
I have also an IC-756 ICOM PROIII among other ICOM equipment. It is good practice when activating any linear amplifier, not just an ACOM 1000, ensure that the relays do the switching linear cold. That is achieved by introducing a time delay circuit in the transmission between the activation of the power amplifier and the transmitter. This will always relays switching work in cold and without power and your life will be much more durable. This advice is very important for the older linear amplifiers where the switching time of their relays may be slower.--- In acom-list@yahoogroups.com, "Tim" <gerald@...> wrote:

5201. New acom2000a arrived, RCU troubles

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-08 17:12:40 UTC
From: Philippe ON4VP
Topic: 5201 Message: 5201

Hi Group,

Not that happy today after spending tons of money and waiting weeks and weeks.
Today the Acom2000a arrived.

All went well (installation). Main voltage setting, installing the transformer, powering up.
The new RCU looks nice and has a lot of info, can be overwhelming at first.

But most annoying thing: IT DOES NOT SHOW pOUT or pRFL.
All the rest is working (antennas, temp, infoscreen, etc...) but the main led bars don't light up.
I've called my dealer, it's all new to everybody, and the manuals are not yet finished. So no idea.

Have to wait for news from Acom Bulgaria.
Sad story after spending that amount of money.

Lucky for me I got the powermaster II at the same time so I can monitor if power output is ok.
Also powermaster II is not 100%. The software crashes all the time (on 4 computers) when com port is selected.

Man, man, I need a beer...
Phil.

Topic: 5201 Message: 5202

Sorry to hear you're having trouble.

First:

The new RCU should default to displaying RF output without doing anything
to it.

Second:

A software issue with the Power Master II is most likely related to your
computer and the USB driver you have loaded. To get the correct driver,
you can go to:

http://www.ftdichip.com/Drivers/VCP.htm

Also, make sure you have the latest version of the PM2 Software here:

http://www.arraysolutions.com/Downloads/PM_Software/PMBasic2_2.0.0.7.zip

5203. new RCU update, works FB after new manual

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-08 20:10:09 UTC
From: Philippe ON4VP
Topic: 5203 Message: 5203

Hello

Glad to hear that Acom Bulgaria responded VERY FAST. Nice service.
Only two hours after I emaild my dealer I got new from Val !!

The problem was that the new manual was not sent with the amp.
They only have it in PDF for the time being and I overlooked a new cabling
that have to be done !!!

The new cable between the RCU and the amp has two extra rca plugs, the HAVE
TO GO in the key in and out at the back of the amp.
If not, pOUT and pRFL will not show.

So the keying line now goes not to the back of the amp anymore but have to
run towards the RCU.
Well that means more wire to the RCU. But it works as advertised.

I will upload the new manual to the file section.
Back to happy camping.

73 Phil

Bob,

1/ RCU

Thanks to Val I got the new manual. I checked and cabling is different. Key in/out must run to RCU and not direct to amp. That was my mistake. All ok now.

2/ PowerMaster II.

Solved. Serial cable ok, I was using older software, my mistake. Latest software runs fine. Call programmed on display.

Tnx, Phil.

5206. ACOM 2000A CAT RCU

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-08 22:26:34 UTC
From: D G
Topic: 5106 Message: 5206

I am looking forward to this new ACOM 2000A RCU.
Any idea when they may arrive and ship in USA ?

73,

Dennis
N3DG

To: acom-list@yahoogroups.com

Subject: RE: [acom-list] Re: Acom 2000A "new RCU" controller

The new RCU is supposed to ship very soon. My understanding is that publishing the new manual is the only thing delaying shipment now.

There have never been any published or announced expected shipping dates, so there have been no (3 times in a row?) delays in delivery. All of this is just speculation by your dealer.

There is no reason not to use the original RCU with your amplifier. It's not like the amplifier is useless without the new RCU.

Originally, it was expected that the 2000A would continue to ship with the original RCU and that the new RCU would strictly be an option.

There has been a change in plans and that is that new 2000A amplifiers will begin shipping with the new RCU only very soon.

The development and perfecting of the new RCU has taken long enough that Acom has decided not to produce any more of the original RCU and the Acom warehouse stock level of the original RCU is depleted enough that they have made a change in plans.

The new RCU will still be available alone as an upgrade option to all existing 2000A owners, as originally reported. All of this will happen very soon.

Also, I have not heard anything from Acom regarding the 800S being available any time soon. I think this also may be pure speculation by your dealer - but time will tell.

The new RCU offers new capabilities in interfacing with your radio and for remote control. In addition, you can see much more data on the beautiful color screen at one time without pressing buttons and navigating menus as you have to on the original RCU. You are correct that the amplifier chassis is not changed whatsoever at this time. Eventually, the connection required by the original RCU may be removed, but at present there is no announced

plan to make those changes. So, all new amplifiers will continue to work with either type RCU - original or the new color one.

Is upgrading worthwhile? Each 2000A owner will have to make his own decision.

Subject: [acom-list] Re: Acom 2000A "new RCU" controller

I know for sure they having some problems with the new RCU's colour display. Acom delayed the delivery of the first shipment already 3 times in a row according to my dealer. I ordered the Acom2000a with new RCU but Acom won't ship to the dealer network until they are satisfied. I'm getting worried. I hoped to have the amp on my bench for the upcoming CQWW but Acom emailed my dealer this week saying another delay will hold shipping until 25th of october. The amp will never get here in time. I'm waiting over 8 weeks now. If I had other options this week, I cancelled my order but options are rare. CQWW barefoot? No, thanks...

As from what I've been informed, the amplifier itself remains unchanged. Only some new functionality on the RCU and the new colour display is different.

Also the Acom 800s should be available around this time.

Subject: RE: [acom-list] Re: Acom 2000A "new RCU" controller

The new RCU is supposed to ship very soon. My understanding is that publishing the new manual is the only thing delaying shipment now.

There have never been any published or announced expected shipping dates, so there have been no (3 times in a row?) delays in delivery. All of this is just speculation by your dealer.

There is no reason not to use the original RCU with your amplifier. It's not like the amplifier is useless without the new RCU.

Originally, it was expected that the 2000A would continue to ship with the original RCU and that the new RCU would strictly be an option.

There has been a change in plans and that is that new 2000A amplifiers will begin shipping with the new RCU only very soon.

The development and perfecting of the new RCU has taken long enough that Acom has decided not to produce any more of the original RCU and the Acom warehouse stock level of the original RCU is depleted enough that they have

made a change in plans.

The new RCU will still be available alone as an upgrade option to all existing 2000A owners, as originally reported. All of this will happen very soon.

Also, I have not heard anything from Acom regarding the 800S being available any time soon. I think this also may be pure speculation by your dealer - but time will tell.

The new RCU offers new capabilities in interfacing with your radio and for remote control. In addition, you can see much more data on the beautiful color screen at one time without pressing buttons and navigating menus as you have to on the original RCU. You are correct that the amplifier chassis is not changed whatsoever at this time. Eventually, the connection required by the original RCU may be removed, but at present there is no announced plan to make those changes. So, all new amplifiers will continue to work with either type RCU - original or the new color one.

Is upgrading worthwhile? Each 2000A owner will have to make his own decision.

5209. A2000A new RCU

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-09 17:55:08 UTC
From: Philippe ON4VP
Topic: 5209 Message: 5209

Hi folks,

The new Acom2000a had his first test run today. After the cabling was altered the display works great.
A lot of new information is right there for the operator.

The new manual also provides a lot of schematics to interface all brand radios to the CAT connection.
Most models are covered. I successfully wired the output from the Microham MKII and/or Station Master (CI-V output port) to the RCU and the amplifier not follows the radio (dialing over the band of switching to other band).
If you have pre-tuned the amplifier to all your antennas and band segments, no more tuning is done, you change band or freq on the radio and the Acom2000a is set and ready to go. Nice !

I'm not using the band decoder output on the RCU. It is designed for the Acom remote antenna switch. But it does provide switching antennas from the RCU, also automated with CAT information from the radio. (I use the Microham Station master to turn and switch antennas). Nice is that you can program your call sign and 10 different names for antenna labels.

I tried to upload the new manual but it failed due to file size.
I will post some images in a folder in this group tonight and please *find this link to download the manual*<http://motoblog.be:8888/web/acom/a2000_newrcu.pdf>from my server.

If you go to Lowes or Home Depot (etc.), find where they sell the vacuum cleaners and there will be many replacement filters of many materials. You can pick & choose what looks good, cut it to size with scissors. Sandwich it in the filter housing or use some duct tape to get it placed where you need it. Be sure to avoid a filter that is "so clean" it won't let the amp breathe.

Easy. Cheap.

From: Philippe ON4VP
Topic: 5213 Message: 5213

Hi group,

One of the new exciting things I love about the new RCU (+ software) is the ability to automatically tune up for USER band segments.
In my case using the CI-V cat control from my IC-7600 according the new manual you just have to select the correct antenna, push the TUNE button on the RCU and the Acom2000a takes care of the tuning.

Once the TUNE button is pushed, the radio is set to 15 watt drive, send carrier and the Acom can tune the load to the antenna. Once done (1 to 2 sec) the radio goes back to rx, the settings are stored and the display changes from DEFAULT to USER.

I've done that for all my 3 antennas on all bands. USER settings are stored. All was done in two minutes. All works just with the push of '*one*' button. Thanks to* CAT control* some nice features are available to the operator !

I was using my 2000a on 12 meters phone this morning and got the following error:

Error: E10: QSK BREAK-IN FAULT, CPU CONFLICT
Amp is off & cooling down!

I've restarted the amp and it appears to be working as expected. Can someone point me in the right direction on what might have caused this error? Also is there a list of the errors and what they mean?

Othere than this odd event the amp has been working great since I put it into service a couple of weeks ago.

Thanks
Rick - ND4P

I note in the manual that the K3 interface is specified at 19.2K.
Unfortunately just about everything that hooks to the K3 wants 38.4Kbps.

Can this be altered in the RCU?

Just recently became the proud owner of an Acom 1000. While looking at some of the older posts I came accross an advertisement for an Acom W5K Wattmeter.

Does anyone know if this meter is still in production and available? Can't seem to find any information on it.

Just recently became the proud owner of an Acom 1000. While looking at some of the older posts I came accross an advertisement for an Acom W5K Wattmeter.

Does anyone know if this meter is still in production and available? Can't seem to find any information on it.

We had a prototype unit that we showed in Dayton a few years ago, but I don't think it was ever put into production.

Well, the W5K Wattmeter may not have made it to the shelves of your favorite radio emporium, but Old Bob and Jay have something called a PowerMaster II that is about as slick and as useful as any device I could ever imagine having for that purpose. Check out the PowerMaster II. I have one and it is a fine thing. Vic, W4VIC

I too have a PowerMaster and like it very much. Mine is the "old" version - today I would of course bye PowerMaster II. The old version requires refreshing the display from time to time (last point in the menu) in order to have a uniform brightness across all segments. Remember this option if it is needed in the mark II also.

Best regards

The Power Master II uses a completely different, hi-tech LCD display which does not require a "refresh" as did the older VFD (Vacuum Fluorescent Display).

Date: 2012-11-24 20:04:52 UTC
From: Bruce Meier
Topic: 5228 Message: 5228

During the CQWW CW test my ACOM 2000A decided to start to register a Protection Fault on 10 meters. This is the only band where this fault occurs . Through process of elimination (using my other amp - Ameritron 1500) the Six Pack / Stack Match / 3 antennas are all working fine. The ACOM works fine on all bands except for 10 mtrs. It works fine on 12, 15, 17 and 20 using the same Log that I use on 10 - through the same Six Pack / Stack Match. I also have a 4 element M2 and a Cushcraft A3. All work on the Ameritron - all FAULT on the ACOM

Any suggestions as to where or what I should start looking?

Thanks,

Bruce - N1LN

OK.

It is very likely that there is something in your antenna system that is arcing and whatever it is may only be affected by 10m RF.

You have to remember that your other amplifier has no ability to detect such things, so it doesn't "know" that something is wrong nor can it report such a problem.

Why it's only showing up on 10m is indeed a mystery, but the 2000A reports these things pretty accurately.

I fully agree with Bob on this one. We have often found the amp Arc
Fault error is absolutely correct about bad connections somewhere in the
RF path. It is true that other equipment will work fine - transmitting
right through the problem - and during a contest, the best option may be
to stick with the equipment that works. It'll probably turn out to be a
bad switch relay contact somewhere in the 10m RF path.

Topic: 5228 Message: 5233

There is something unique to your 10M antenna system that is making the Acom puke. It could be a connector, coax switch, barrel connector, tuner/ SWR bridge, just about anything in in the path between Acom and antenna.

The Acom may appear to be "evil" for reporting this, but believe me it is faster and smarter than any human, and will protect itself. If it is seeing what it calls an "ARC FAULT" there is really something there, even if you other amplifiers are oblivious to it. Many Acom owners have had this issue from time to time, but with enough trial-and-error and component substitution, they always find out what was wrong. And the amplifier is always right, although sadly it cannot pin you down to the exact point of failure.

Thing to do is make a detailed diagram of your 10M coax segments, connectors, etc. If there's anything you have doubts about, start there (coax switches, splices, cheap connectors, water-laden coax are notorious). Otherwise, begin substituting a dummy load and do segment tests along your transmission line. You will probably find something that is intermittent or outright faulty, and the Acom is only genius in the house!

Let us know what you find.

Good luck and 73

Dan
K0DAN

PS Wouldn't hurt to do the manual tune procedure using Acom and all your 10M cabling into a 50 ohm dummy load. Once the Acom is manually pre-tuned for 50 ohms, see if the problem still exists. But my bet lies with the rather elaborate switching matrix you have with the stack switcher, coax switches, and various coax segments in your station. I have had much simpler segments also cause an ARC FAULT.

Exactly, had that once as well, ended up being a hand-tightened (but not enough) connector. Thanks to the ACOM 2000A, I discovered a loose PL-259 and right-angle coaxial adapter, and after I wrench tightened all connectors, cables, patch cables inside and outside...problem solved.

Had that fault on my vertical....

followed the advise to " trust the amp"

Indeed with a good dummyload... at a connect point before leaving the
basement it was still ok .....

the line outside had gone bad with moisture,,,,
after all it was 16 years old and buried....it was NOT burflex.

one smart amp...

Thanks to everyone that responded. Also, thanks to ACOM for building a piece of test equipment that doubles as an amplifier. The trouble was located and resolved, but more testing will be required to be sure. So far I have been using the new coax for about 1 hr and no Faults.

After some troubleshooting I determined that the coax from the Six Pack to the Stack Match was bad. It required a couple tower climbs on a mid-40 F / 12 mph wind day to first eliminate the Stack Match and then replace the coax. The bad coax was a piece of LDF4-50 that I purchased used about 9 years ago and spent the last 6 years in an underground conduit. The temporary replacement is LDF-400 and running on top of the ground. It is too cold and windy to pull the hard line out of the conduit, but just right to climb the tower a few times J !!

I fully agree with Bob on this one. We have often found the amp Arc Fault error is absolutely correct about bad connections somewhere in the RF path. It is true that other equipment will work fine - transmitting right through the problem - and during a contest, the best option may be to stick with the equipment that works. It'll probably turn out to be a bad switch relay contact somewhere in the 10m RF path.

It could be that something about your antenna / transmission line system presents a highly reactive load at 10 Meter frequencies, generating sufficient voltages somewhere along the line to cause arcing. If you have any right-angle coaxial connectors anywhere in the line, I'd start by removing those, and then determine whether that eliminated the problem.

Subject: Acom Fault

Several years ago I had an error message indicating high plate voltage on my 2000. I pretty much ignored it until I had a shutdown which forced me to take action. After several voltage measurements I found a 20% over voltage.
I found the same at the outlets throughout the house..It was late at night but was able to contact the power company. First response was, We'll check it on Monday (it was a Sat nite). My reply was, remember you're responsible for any burnt out appliances or fire. They arrived a few hours later that night. I spoke to the linemen who were changing the pole transformer. They said there was a problem with a winding. Acom was the hero and could be considered a new piece of test equipment.

5239. Acom 1000 Error Codes

Yahoo group: acom-list (2010 — 2016)
Date: 2012-11-28 17:55:53 UTC
From: Irwin Darack
Topic: 5239 Message: 5239

My Acom 1000 amp stopped working in the CQWW CW contest this weekend and I would appreciate any assistance in diagnosing.
Amp: Serial Number: 020175
Tube - Original: Serial Number: 4128/11
Purchased: 5/18/2002
Running: 240 volts
I had been using the amp in the contest, took a quick break and placed the amp in stand-bye (Operate Off). When I came back, the amp was turned off. I am able to turn the amp back on, but it will no longer tune. The SWR into my dummy load is 1/1 when I am in Stand-Bye (Operate Off), but goes to infinity when I am in Operate Mode. I had a spare amp, which is working fine, so I know that my other components are working fine.
I would apprecite any asisance in diagnosing the amp.
Here are the error codes I am getting from the LCD:
1ASB2E 000000 000000
1BB298 0720DC DF7FF9
2ASB2B 000000 000029
2BB499 0720D8 D77FDE
3ASB27 000000 000000
3BD3B2 0720DC D77FB3
4APN05 000000 000600
4BA19B 0400DE DF7EE4
5ASB27 000000 000000
5BD1B3 0720DC D77FBO
6APN07 000000 000000
6B0097 0400DC DF6E5D
7APN07 000000 000000
7B0097 0400DC DF6E5D

Thank you, Irwin KD3TB

The error code indicates a Power Supply problem in either the +5 or 24v
power supplies and that it occurred while in standby. More in-depth
trouble shooting will need to take place to narrow it down further.

The error codes give you a hint where to look - not how to repair the amp
specifically.

5243. ACOM 2000A CAT RCU, Added Value & Features, Coming to USA

Yahoo group: acom-list (2010 — 2016)
Date: 2012-12-06 03:16:45 UTC
From: n3dg
Topic: 5243 Message: 5243

After a brief fling with a foreign solid-state amplifier, I was gratefully reunited with another new ACOM 2000A (I should have never sold my first one). I considered the super-nice OM Power OM2500A which is now available with some more horsepower, but nothing runs as quiet as the ACOM 2000A which has proven itself over a long legacy:

http://www.arraysolutions.com/Products/OM_Power/OM_Power.htm

To cover 6 Meters, I also added a new sibling, the ACOM 1500 dedicated to 50 MHz and as an HF backup.

http://www.arraysolutions.com/index.html

I have been very jazzed by the ACOM 2000A Remote Control Unit which adds CAT Frequency Tracking and many other features and user-friendliness to the ACOM 2000A which has evolved and been perfected over more than a decade. I just saw this new video and sexy pics:

http://www.youtube.com/watch?v=_q0UuMRcaNQ

http://www.arraysolutions.com/Acom/NEWRCU.htm

The new ACOM CAT RCU in one small package, takes any newer or older ACOM 2000A to a new level of functionality and features and has modernized the amplifier for this decade with even more advantages over other US and EU HF QRO Amplifiers.

I just placed my order with Array Solutions via website:

http://www.arraysolutions.com/Products/acom.htm

I understand Jay & Bob will be handing them to Santa to deliver by Christmas...can't wait !

Learn from our experiences.
Pennradio/N3DG/ D. Gazak has been picking up a very unsavory reputation on ebay as well as other online trading facilities. From what I understand he has been banned from selling on at least one amateur radio site. I had the misfortune of buying a power supply from him. I received over 20 demands for payment in the first two days after the auction. I paid him VIA Paypal (luckily) including a ridiculous $50 to ship an 11 pound item. (Actual shipping cost was close to $12) The item arrived severly damaged due to the very lame "packing" job. He claimed the item would be PROFESSIONALLY packed. It was not. The item was stuffed into a well used box with used air pillow packing. Of course the air pillow beccame puntured allowing the item to flop around and become damaged. When it arrived damaged he refused to accept any responsibility and ordered ME to file a claim with the shipper. Of course the shipper will not pay off on inferior packing. The seller is RUDE and abusive.

I filed a Paypal claim and was awarded a refund after Paypal reviewed the case. The item was returned, packed far better by me than I had received it. When Mr. Gazak received the DAMAGED power supply he simply relisted the DAMAGED supply on ebay and re-sold it. I later saw the same power supply for sale on ebay. The damaged power connector was the tip-off. I contacted the new owner and compared notes. The new owner thougt the damage occured when the item was shipped to him. He had no idea the damage was existing but concealed at time of sale. He also said that pennradio offered to send him a matching transmitter in the future in exchange for posting favorable feedback !

Please do a web search of N3DG before experiencing a deal with this guy ! Check out his feedback on QTH.com and READ his negatives here on ebay. Heed the feedback!

New price with the new controller - $7950
Price last week with the old controller - $6850
Price for new controller alone - $900

What am I missing? I would have been better off and ahead of the game if I purchased one last month and then added the new controller after the fact. I would have saved $100 AND had a spare controller!

I was waiting to buy once the new controller was available. I guess that was a bad call. I expected maybe a small increase for the new controller, but not $1100!

I may now re-consider an Alpha 9500. Or wait to see what the AN Wireless group (ex Command Tech / Palstar) has to deliver next year.....

Subject: [acom-list] ACOM 2000A CAT RCU, Added Value & Features, Coming to USA

After a brief fling with a foreign solid-state amplifier, I was gratefully reunited with another new ACOM 2000A (I should have never sold my first one). I considered the super-nice OM Power OM2500A which is now available with some more horsepower, but nothing runs as quiet as the ACOM 2000A which has proven itself over a long legacy:

http://www.arraysolutions.com/Products/OM_Power/OM_Power.htm

To cover 6 Meters, I also added a new sibling, the ACOM 1500 dedicated to 50 MHz and as an HF backup.

http://www.arraysolutions.com/index.html

I have been very jazzed by the ACOM 2000A Remote Control Unit which adds CAT Frequency Tracking and many other features and user-friendliness to the ACOM 2000A which has evolved and been perfected over more than a decade. I just saw this new video and sexy pics:

http://www.youtube.com/watch?v=_q0UuMRcaNQ

http://www.arraysolutions.com/Acom/NEWRCU.htm

The new ACOM CAT RCU in one small package, takes any newer or older ACOM 2000A to a new level of functionality and features and has modernized the amplifier for this decade with even more advantages over other US and EU HF QRO Amplifiers.

I just placed my order with Array Solutions via website:

http://www.arraysolutions.com/Products/acom.htm

I understand Jay & Bob will be handing them to Santa to deliver by Christmas...can't wait !

73,

Dennis

Eric,

You're not missing anything and yes, you could have saved a few hundred dollars had you bought one before we sold out of the original units.

The 2000A was underpriced and represented probably the best bargain in ham radio for a long time.

At the same time that the new RCU was introduced, Acom has decided to increase the base price of the amplifier, which they have not done for nearly 10 years.

Price increases will follow on the 1000, the 1010, and the 1011 at some time in the future. The new 1500's price will not change as it is part of the new pricing structure from Acom already.

Before you consider an Alpha 9500, you need to look at how the 2000A is still better from several perspectives.

Read the comments from those who had a 9500, sent it back for a refund, replaced it with an Acom, and wished they had not wasted their time with the Alpha.

New price with the new controller - $7950
Price last week with the old controller - $6850
Price for new controller alone - $900

What am I missing? I would have been better off and ahead of the game if I purchased one last month and then added the new controller after the fact. I would have saved $100 AND had a spare controller!

I was waiting to buy once the new controller was available. I guess that was a bad call. I expected maybe a small increase for the new controller, but not $1100!

I may now re-consider an Alpha 9500. Or wait to see what the AN Wireless group (ex Command Tech / Palstar) has to deliver next year.....

John,

Acom is not happy with the development of the 800S.

The 800S was announced at Friedrichshafen in 2011, and it was expected that the amplifier would be ready to go around the beginning of 2012 and we all know that did not happen.

What we have been told recently is that Acom has not been able to achieve the level of reliability and robustness in a solid state design that Acom is known for with the rest of their amplifier products. While not having the 800S has been disappointing, had it been released, and resulted in costly failures, none of us would have been happy.

Acom is still working on refining a solid state amplifier design, and the first model released may be rated at a lower power level - maybe 600 watts.

In the meantime, the Acom amplifier line with tube finals is the best you can buy.

Thank you for your prompt response. I am a very happy owner of an Acom 1000, but for various reasons I had an interest in an Acom quality solid-state amplifier. I agree 100% with the idea of avoiding a less than reliabile amplifier.

Hello all,
one of 2 ACOM2000A US type ceramics fuses (back side) 20A/250V/314 is broken.
My question: what type of fuse is it (fleet or slow) ?
May I replace it by EU type glass fuse 20A/250V ?

Thank You for response.

Thomas
I would suggest a slow type as there will be a peak when the transformer is switched on. But to be safe you could start using a slow type. But do try to use a ceramic type to avoid an exploding glass type.

These are not "slow blow" fuses.

From the 2000A manual (page 25):

The two Primary Mains Fuses of the amplifier are located on the rear panel. They are 20A/250V Quick blow, 1-1/4 x 1/4 inch Cartridge Fuses, Size "0" Ceramic.

Thomas,

I am way behind with my email. I am assuming you got an answer for this?

Unless it is the only fuse you have, don't you use glass at this high a voltage and current. Ceramic fuses don't explode. Glass can explode and make a mess. The fuses are 20A ceramic quick-blow.

73,

N2TK, Tony

Thomas,

I am way behind with my email. I am assuming you got an answer for this?

Unless it is the only fuse you have, don't you use glass at this high a voltage and current. Ceramic fuses don't explode. Glass can explode and make a mess. The fuses are 20A ceramic quick-blow.

73,

N2TK, Tony

Subject: [acom-list] ACOM2000A fuse (spare part)

Hello all,
one of 2 ACOM2000A US type ceramics fuses (back side) 20A/250V/314 is broken.
My question: what type of fuse is it (fleet or slow) ?
May I replace it by EU type glass fuse 20A/250V ?

Thank You for response.
73 de Thomas, DL1AMQ

ACOM 2000A's work on 30M unless they are broken. Full output: 1500W. There is no "USA" amp.

ACOM 2000A's don't cover 6M.

73,

Hal N4GG

It sounds like your radio is not putting out any RF to the amplifier.

Do you have the 30m output on your radio connected to the amplifiers' input?

Some radios (like Icom) have the antenna 1/2 switch and it could be in the wrong position.

USA Acom 2000A units are the same as in any other region - no difference.

The radio (icom 7800), works perfectly in 30mt too, and the Amp display reads the right frequency.

If I overdrive the Amp, at some point the RCU drive LED lights. But forward power LED bar graph remain off, and no power goes to the antenna.

As previously reported by others, in the USA there is a 200W PEP limitation on 30M operation, so use of the ACOM is kind of a moot point.

However out of curiosity I switched to the dummy load and keyed the ACOM 2000 with about 50W drive and the wattmeter showed full output (~1500W). This is a 1999 vintage ACOM.

Not sure what is legal power limits in your country, but have you tried the TUNE procedure for that band?

Since you are only having that problem on 30M it is worth trying the manual tune. It might not be the cause of your problem, but it can't hurt to try it.

Once you "teach the amp the tune parameters for each band, then the procedure is thereafter automatic unless your antenna load/freq/band changes dramatically.

Assuming your 30M antenna is a 50 ohm load, connect the amp to a dummy load and follow the instructions in the manual. This procedure is on page 18 of my manual.

If you don't have a manual, they are available on the archives, or I'll email you a copy.

5280. ACOM 2000A, 30m problem, back to basics

Yahoo group: acom-list (2010 — 2016)
Date: 2012-12-29 19:18:55 UTC
From: Norman
Topic: 5267 Message: 5280

Lots of ideas and suggestions but there are some basic steps that can be taken to localize the problem.
1-First determine if the 7800 is putting out power on the 30m band AND on the proper antenna output connection.
===> The comments below suggest that the 7800 is transmitting okay.
-2 Do you have a separate Watt meter that can be connected to the ACOM output? If so hook that up and set pwr level to 200w or so.

3-Then check that that the IC 7800 pwr output can be read on that meter with the ACOM in Standby. If so, the connections are correct.

Although the ACOM is auto tune, and metering not readily visible, input power, grid drive, Plate Current and Output power are available via TCU menu. So just follow the steps one would do if this were a manual tune amplifier. I would first check the characteristics of the amp on a band that is working, 40m would be my choice, then follow this procedure:

-slowly advance the drive (pwr control on 7800) and watch the Grid Current, it should rise with just a few watts at most. If that goes up, then check the plate current, it should also increase, and some Pwr Output should be indicated on the watt meter. Set the 7800 drive for at least 100w output on the external meter, also check the internal meter RF output reading. Note the Grid Drive and Plate current.

Then change bands, to 30m, and go through the same procedure. Note the 7800 drive power, the 2000A grid current, and Plate current and the resulting output power. If the grid current rises, then drive is being applied, and if plate current rises one can assume the band switch connections are not defective. Power out put should also be read both externally and internally and be similar to the 40m readings. If none of the above happens I would suspect some fault in the band switch connections. If the grid drive goes up and plate current changes, but not in the linear way it does on 40m and Po is not seen I would then follow the procedure for MANUAL tuning as one would do with a old fashion manual tune amp. Adjust the plate looking for a DIP in current, and rise in output power. If power out is achieved, but with a gross change in the settings I would be concerned that there is still a band switch connection problem.

Hope this helps - it is what I would do on my 2000A if similar issue occurred.

I know that Acom produce a mod kit for 60M operation for the 1000, but power limits really don't warrant it. We in the UK will be limited to 100W erp from Jan 1st

5282. R: [acom-list] ACOM 2000A, 30m problem, back to basics

Yahoo group: acom-list (2010 — 2016)
Date: 2012-12-30 12:21:28 UTC
From: ik2typ
Topic: 5267 Message: 5282

Hi Norm

I followed the procedure you suggested connecting a dummy load to Amp RF out, before in 40 and after in 30mt where I recognized that i-plate raised too much just with a bit driving RF (due to a not matching load). So I went into the Auto tune Submenu and made an USR-tunings procedure in the 10.100 ☐ 10.200 frequency segment and so that problem went by.

Still I don☐t know why the former matching data about this segment went lost, but now everything runs perfectly from 160 to 10 mt.

I can only wish an happy new year 2013 to everybody

Oggetto: [acom-list] ACOM 2000A, 30m problem, back to basics

Lots of ideas and suggestions but there are some basic steps that can be taken to localize the problem.
1-First determine if the 7800 is putting out power on the 30m band AND on the proper antenna output connection.
===> The comments below suggest that the 7800 is transmitting okay.
-2 Do you have a separate Watt meter that can be connected to the ACOM output? If so hook that up and set pwr level to 200w or so.

3-Then check that that the IC 7800 pwr output can be read on that meter with the ACOM in Standby. If so, the connections are correct.

Although the ACOM is auto tune, and metering not readily visible, input power, grid drive, Plate Current and Output power are available via TCU menu. So just follow the steps one would do if this were a manual tune amplifier. I would first check the characteristics of the amp on a band that is working, 40m would be my choice, then follow this procedure:

-slowly advance the drive (pwr control on 7800) and watch the Grid Current, it should rise with just a few watts at most. If that goes up, then check the plate current, it should also increase, and some Pwr Output should be indicated on the watt meter. Set the 7800 drive for at least 100w output on the external meter, also check the internal meter RF output reading. Note

the Grid Drive and Plate current.

Then change bands, to 30m, and go through the same procedure. Note the 7800 drive power, the 2000A grid current, and Plate current and the resulting output power. If the grid current rises, then drive is being applied, and if plate current rises one can assume the band switch connections are not defective. 5284. GU74B plate dissipation and Acom 1000 power output

Yahoo group: acom-list (2010 — 2016)
Date: 2013-01-02 05:10:12 UTC
From: krishna kumar
Topic: 5284 Message: 5284

Howdie,
 I am playing with an Acom 1000 and is hooked to a Daiwa cn-720B.
 i see that on peak tune up, the amp puts out a little over 800w per the Daiwa,
but the display on the Amp shows just a tad bit over 1000w. This is observed
 on 20m, 15m bands. Have not tried the other bands as yet.

With a plate dissipation of 800w from the 4CX800/GU74B, is one supposed to
expect 1000w PEP or Carrier keydown like is mentioned in the manual?

what is everyone else getting on the Acom 1000 as seen with an external watt meter?

May be i need a new tube? Age of the tube in the amp is unknown.

The amp is on 240V. The amp is so quiet as compared to my TL-922.

Krish,

I strongly suspect that your Daiwa wattmeter is not accurate.

Yes, the Acom 1000 typically will put out 1 kW and it will exceed that amount if you push it a little harder.

Pushing it harder is NOT recommended as it will shorten the life of the tube.

you will need a peak reading watt meter My 1000 show 1100 watts on 75
meters 1000 watts on 10, I am sure if check the specs on your meter it
doesn't show peak reading. I am using a Alpha 4520 and array- solutions meters
their within 20 watts of each of each other.

Date: 2013-01-02 13:43:37 UTC
From: Kees - pa7two
Topic: 5284 Message: 5287

Hi Krishna,

Some example data from one out many Acom 1000 units I repaired / measured:

****

PA7TWO 11-11-2005 16.39 GMT ACOM 1000

Spinner 1KW Dummy-load
50 ohm.

Transformer taps set
on 230 volt.

A/C Main in house 221
volt, under load 219 volt

Freq: Input: Output: Tune: Load:

1.830MHz 60watt 968watt 76 74

3.600MHz 60watt 903watt 48 69

7.020MHz 60watt 850watt 61 73

10.140MHz 60watt 850watt 20 28

14.040MHz 60watt 924watt 51 28

18.100MHz 60watt 913watt 83 73

21.040MHz 60watt 903watt 35 52

24.950MHz 60watt 861watt 82 64

28.110MHz 60watt 913watt 45 47

Measured at 28.500
MHz:

Plate Current: 600ma

Plate RF Peak: 2112volt

DC Power Input: 1340watt

High Voltage: 2624volt

SWR 1.0

Reflected power 0

Forward power 913 watt

Exh Air 34C

Screen Current 31ma

RF Power Gain 12.0 db

****

In general one can say that these values as stated above are 'average' values. Your tube is designed for about 750-800 Watt output, depending on the specifications brochure version from Svetlana. An Acom 1000 can certainly RF peak above 1000 Watt when using in example CW code. However, running the tube above 800 Watt is simply asking for trouble. Also the GU74B tube RF output over time does wear-out slightly, especially when the amp has been used with possible maximum output. Furthermore, digital modes are "killing" for these amp when used with high RF output levels anyway. The values mentioned above are with a fresh 24 Hours burned-in GU74B tube and key-down.

So, if your Daiwa power meter is metering at the low end, or the GU74B tube has been used hard, your measured values are as they expected to be.

What is the RF input power you used?

Subject: [acom-list] GU74B plate dissipation and Acom 1000 power output

Howdie,

I am playing with an Acom 1000 and is hooked to a Daiwa cn-720B.

i see that on peak tune up, the amp puts out a little over 800w per the Daiwa,

but the display on the Amp shows just a tad bit over 1000w. This is observed on 20m, 15m bands. Have not tried the other bands as yet.

With a plate dissipation of 800w from the 4CX800/GU74B, is one supposed to expect 1000w PEP or Carrier keydown like is mentioned in the manual?

what is everyone else getting on the Acom 1000 as seen with an external watt meter?

May be i need a new tube? Age of the tube in the amp is unknown.

The amp is on 240V. The amp is so quiet as compared to my TL-922.

73s

Thank you Kees,
The data is very convincing and i will go ahead and pick up a replacement tube for a spare and try it out.

I drive it with about 57 to 60watts and i know that it has saturated, since any additional drive does not
increase the output even with an attempt to peak the output (tune/load). So i back off the overdrive attempt.

On 17m, the Tune/Load settings that i observed for Max output is inline with your data and is
contrary to what the manual states, which is 61-63 for Tune and 54-52 for Load.

thanks again & 73s

Subject: RE: [acom-list] GU74B plate dissipation and Acom 1000 power output

Hi Krishna, Some example data from one out many Acom 1000 units I repaired / measured:**********
PA7TWO 11-11-2005 16.39 GMT ACOM 1000

Spinner 1KW Dummy-load 50 ohm.

Transformer taps set on 230 volt.

A/C Main in house 221 volt, under load 219 volt

Freq:	Input:	Output:	Tune:	Load:
1.830MHz	60watt	968watt	76	74
3.600MHz	60watt	903watt	48	69
7.020MHz	60watt	850watt	61	73
10.140MHz	60watt	850watt	20	28
14.040MHz	60watt	924watt	51	28
18.100MHz	60watt	913watt	83	73
21.040MHz	60watt	903watt	35	52
24.950MHz	60watt	861watt	82	64
28.110MHz	60watt	913watt	45	47

Measured at 28.500 MHz:

Plate Current: 600ma
Plate RF Peak: 2112volt

DC Power Input: 1340watt
High Voltage: 2624volt
SWR   1.0
Reflected power   0
Forward power   913 watt
Exh Air   34C
Screen Current   31ma
RF Power Gain   12.0 db**********In general one can say that these values as stated above are 'average' values. Your tube is designed for about 750-800 Watt output, depending on the specifications brochure version from Svetlana. An Acom 1000 can certainly RF peak above 1000 Watt when using in example CW code. However, running the tube above 800 Watt is simply asking for trouble. Also the GU74B tube RF output over time does wear-out slightly, especially when the amp has been used with possible maximum output. Furthermore, digital modes are "killing" for these amp when used with high RF output levels anyway. The values mentioned above are with a fresh 24 Hours burned-in GU74B tube and key-down.So, if your Daiwa power meter is metering at the low end, or the GU74B tube has been used hard, your measured values are as they expected to be. What is the RF input power you used?Vy 73, de Kees - PA7TWO - M5TWO

With a BIRD 43 with PEP module installed, my ACOM 1000 delivers over 1000 Watts key-down on all bands. Input depends a bit on what band but around 60-65 watts input delivers 1000 watts out. You should see around 12.5 dB gain with 60 Watts in on each band. Except 50 Mhz: the gain on 50 Mhz must be around 13.5 dB. The gain can be read on the display of the Acom. Also you should see > 2700V anode voltage.
PEP read-out can be over 1200W but this should be avoided all time as the GU74B will not have a long live. Keep output a bit less then 900 Watt max in SSB and the tube should be OK for years.

GL and happy new year, Ger PE1CZG

Thanks Phil,
 I have the Acom on 240v and only have a single 240v outlet here(normally used for the Alpha 9500).
 If i could switch the Acom to 110V, then i can run the Acom through the Alpha 9500 (can handle legal limit in bypass) and use the metering on the alpha, since is it much accurate than the
analog Daiwa meter.

At any rate, it appears that i am in for a spare tube at this point.

Krish

you will need a peak reading watt meter My 1000 show 1100 watts on 75 meters 1000 watts on 10, I am sure if check the specs on your meter it doesn't show peak reading. I am using a Alpha 4520 and array- solutions meters their within 20 watts of each of each other.

5292. 2000A New RCU ICOM problem

Yahoo group: acom-list (2010 — 2016)
Date: 2013-01-03 22:18:57 UTC
From: Ralph
Topic: 5292 Message: 5292

Happy New Year to all,
I installed the new RCU to my 2000A today. I am using an IC-7700 with Micro-ham Digi-Keyer II along with the 2000A all 3 into a ICOM CT-17 4 port C-IV box. All works fine when first using it but after a 5 or so minutes the 2000A starts to either hop around bands and/or band segments by itself. This is not transmitting, just sitting not touching anything. With or without a logging program running. Worse with a logging program, I assume due to the polling.
The wiring diagram for the C-IV to the RCU COM connector shows 2 470 ohm resistors, one in each pin of RX/TX. It almost looks like the voltage drop across those 2 resistors is increasing as they, or the RCU as it heats up is affecting the frequency decoding. It works for a while then after 5 - 10 minutes sort of goes nuts. I just did a switch from 40 to 20 meters, it took the RCU 18 seconds to make the move. And, it just hopped to 15.000-15.100 Mhz by itself. All have been on about a half hour
Any ICOM users seen this phenomenon?

Ralph W1ZK

Hello Ralph, I had the same problem with my Yaesu FTdx9000D and making a custom CAT cable (none was available from the reseller yet).
After the "hopping around", the CAT RCU stopped even tracking altogether, it doesn't track at all now.
The problem is not specifically around ICOMs.

Dennis,
I am be getting somewhere with the ICOM. Val LZ1VB at ACOM told me the new RCU, in the case of ICOM, is designed to plug directly into the CI-V jack on ICOM radios. When I did that it worked perfectly. But, I can't use the Microham DK-II for logging & FSK.
I am going to play with the values of the two resistors in the cable I built for the new RCU. When it is plugged into the CT-17 4 port box the signal the RCU sees has to be on the edge at or lower than the +/- 3 volt low voltage standard for RS-232 serial devices.

Ralph,
If you have an older model, you may want to check/replace the charge pump eletrolytics in the CT-17. They have been known to go bad and cause some probs.. I had to do that with mine. A home brew ct-17 found here with detailed circuit description may prove worth the read.

5299. New RCU with my old 2000a

Yahoo group: acom-list (2010 — 2016)
Date: 2013-01-07 00:49:39 UTC
From: hsl@sbcglobal.net
Topic: 5299 Message: 5299

I replaced the old RCU - it had problems, and am very happy with how the new RCU plugged right in.

I am using a K3 but not using CAT.

The only comment I have at this point is that the forward power meter in the RCU has a peak indicator, but the reflected power meter does not appear to have one. It would be most useful there.

Harvey, W8DX

5300. new RCU impression

hi

Been playing around with the new Acom2000a w/the new RCU. First impressions, Really a fantastic unit.

Had the Acom1000 and it works great, wanted to give auto tune a try, hard to believe how fast it tunes very easy to set up, a quiet unit, lots of features can't wait to spend some real time with it.

Worked some good DX with it, still learning some of the new features.

Hoping some others might want to share there thoughts as well....

Topic: 5301 Message: 5301

I will never sell my Acom 2K !

It's the best amp on the market and they just recently went up on the price after 15 years. Unlike others who want to much for their amp, along with parts and service.

The speed in tuning and operation is flawless, the reflector is a wealth of knowledge.

I have the old controller and may pick up the new RCU just for the heck of it, after all the amp is going no where.

I'm fortunate in that Array Solutions is 20 min drive from my home so service is no hassle either.

Life is good with an Acom ! Hey that should be on their website, I just came up with the slogan! Lol !

Time to replace the external fan as it is getting noisy. Presently have a Papst 4214GM, 24V, 2.3W.

Easy to find 4214 4.3W.

What is Acom presently using on the 2000A?

Tnx

5306. 9000,2000a-new rcu, MKII- auto tune??

Yahoo group: acom-list (2010 — 2016)
Date: 2013-01-13 22:36:59 UTC
From: myles
Topic: 5306 Message: 5306

hi

Since the new rcu enables tune activation on the 9000, naturally wanted to try it, but my setup is perhaps a bit 'complicated', however I am convenced not unusual. Thus thought someone might have figured out a way to get the following to work.

My set up : the 9000MP connected to my Mac running MLDX, via the MicroHam MKII.

Not sure how I can add the Acom's serial data in a bidirectional fashion. My first thought was to grab the unused CIV from the MKII however it's unidirectional(would send freq data to the Acom only).

Another suggestion was (if the amp is transparent (is it?)), perhaps simply moving the CAT cable currently connected to the transceiver to the "computer" port
of the amplifier and connect the "radio" port of the amplifier
to the "radio." might work but wonder if anyone has tried it or has some insight to share?

Thanks
N2EHG

From: Bob Naumann
Topic: 5306 Message: 5308

Myles,

Since you want to continue to use the MKII, I would suggest that you temporarily configure the 2000A RCU to use Yaesu CAT and then go through the USR tuning procedure. To do so, directly connect the DB9 CAT port of the 9000 to the DB15HD CAT port of the 2000A RCU as shown in the manual, and go through the USR tuning process without the MKII or your computer connected.

When you have completed the automated USR tuning process (which the amplifier will retain and use), re-cable the MKII to the 9000MP and change the 2000A back to use the CI-V from the MKII.

The RS-232 port on the amplifier itself is not "standard" nor is it usable as apparently suggested to you. In fact, the manual warns:

C A U T I O N
Do not connect to the connector, marked RS-232 a "standard" cable because this may result in damage in both - amplifier or connected equipment. In order to use the RS-232 interface, a special cable must be prepared. Contact your dealer or see TECHNICAL SUPPLEMENT for details".

Hi

Thanks very much for the responce, it would seem easier to just push the button on the front pannel to do the initial tuning, vs making a cable and recabling since in this case it would have to be 'temporary vs long term' and naturally wanting to try out the new amp have done so, amp works great.

I fully understood the amp requires a 'special' cable as per the manual, my below was more of a 'how to ' hook it up vs what cable is needed. but it is a very important safety tip so thanks for the heads up.

it seems from what I am able to learn from Joe, who was very kind to share some data with me, that the CIV port is not mirroring the serial ports by default if I understood correctly in order for the civ port to send data it must be commanded to do so via the software I will keep my fingers crossed that these features can be enabled i would hope that I could at least have the freq data sent to the amp

Mean time thou not connected via serial, the amp is truly fantastic the new controller is amazing and overall just a lot of fun!

thanks again for all your great help

Unless such an announcement comes from Acom, there is no reason to believe it.

There are lots of rumors all the time about tubes no longer being made - all false!

Someone has been circulating false rumors about the 4CX800 (GU74) not being available for years - not true.

Now, there are rumors about the 4CX2500 (GU84) not being available - also not true.

It seems that whenever a competitor to Alpha Amplifiers is doing well, false rumors about the tubes those other manufacturers use comes mysteriously from somewhere unknown.

Myles,

You only have to do the USR tuning once - unless you make a significant change to your antennas.

The amp will store those tunings and automatically recall them when you go back to that same frequency segment - it's not something you would be doing as a routine on a frequent basis - and these tunings apply regardless of how you have your radio interfaced or what type of radio the amp "thinks" you're using.

This is why I suggested the temporary direct connection as Yaesu to facilitate the easier "push the button" method of doing the USR tuning process. Then, you could have your USR settings and your CI-V solution too.

In most cases, where you have good SWR, you do not need to do the USR tuning process at all. The factory defaults are just fine for most users.

There are some cases where you may have multiple antennas per band, or you have a resonant antenna that may be somewhat "narrow-banded" and there you may want to have special USR tunings set up, but this is not the typical station today.

73,

Bob W5OV

Topic: 5315 Message: 5315

Dear all,

I have for sale a ACOM Accessory Remote ON. This device is on page 14 in the link
<http://www.arraysolutions.com/Downloads/Acom/ACOM_2000A_Remote.pdf>
http://www.arraysolutions.com/Downloads/Acom/ACOM_2000A_Remote.pdf

I was inspired by the mail below to buy this device but I now realize that I will not set up a remote rig. Therefore I am selling this device as new.

I am asking 125 EUR including shipping (without insurance).

Please contact me offline at kh@...

Topic: 5306 Message: 5316

Thanks again for all the help really appreciate it, and all your excellent tips as always.

I do have multiple antennas , and multi ant per band, but most are nearly perfect swr but some are just a bit outside of the default. I programed it all in manually where needed. Did this cause I didn't want to make 2 cables :).

The flexibility of the amp for multiple antennas, various segments etc it all works so smooth. I am having a lot of fun w/the new amp the controller is really super

I may have a bit of good news seems the programs I am using may in fact command the civ port to send the freq data so when I get the chance I'll make a civ cable and try it out, it 'should work' w/the set up I have , a fun experiment to try and see if it will send the freq data to the amp.

Thanks for the help be happy to post the results.

5317. Acom 1000 Acting funny

Yahoo group: acom-list (2010 — 2016)
Date: 2013-01-22 22:05:07 UTC
From: Trevor Dunne
Topic: 5309 Message: 5317

Hi all

My 1000 is acting a bit strange, last few times when I turned it on the backlight had reset to off and I had to adjust it up. I also notice when I put the amp in to standby the green LED will flash 2 times and then go out, It never used to do this either.

Anyone have any idea what might be going on.

Thanks
Trevor

Hello All,

During the CQ 160 Meter CW contest
I had this failure twice...

When changing frequency segments on 160
the amp would fault and shut down.

The readout said "LOAD CAPACITOR SYSTEM MALFUNCTION".

Any info or suggestions on this problem would be very much appreciated...

Many Thanks in Advance for any info.

Ted,

The thing to do first is to re-do the user tunings on 160 and see if it persists.

You may have a failure in the load cap drive motor.

These are available from Acom and can be replaced.

Mine did something similar except it did it on all bands! Turned out a grub screw on the driven pulley of the load capacitor had fallen out and was quickly replaced - bit fiddly but easy to do. Contacted factory and they told me how to reset the capacitor. They sent instructions and photos so job was straightforward. Since doing this no more error messages!

5321. Tuning the Acom 1000 with Navigator Interface installed

Yahoo group: acom-list (2010 — 2016)

I have Elecraft k3 radio. After installing the Navigator interface I could no longer get the Load and Plate in balance without ARC fault error message. Using the paddle to generate rf signal does not work so well when going thru the navigator. Is there a remedy for this anywhere out there? Let me know.

Jeff,

Take the Navigator out of your system (disconnect it) and make sure that nothing else is wrong.

As this device should only impact what your radio is doing, for something to appear as a problem in the amplifier makes no sense.

I use a similar device from Rig Expert with my K3 and my Acom 1500 and I have no problems such as you describe.

Something is likely wrong elsewhere.

Hi
Just arrived new RCU for my Acom 2000. Plugged via cat in the ci-v out of the MK II it is runnig well. At the moment seems good, also changing antennas by the switch Acom. Finally it is running in the correct way.
I note that is a little slow....but not bad. Now it needs to be tested in contest all band.

Hello Gianni,
*
I too have purchased the new RCU for my ACOM 2000 from the American distributor. Playing with the new RCU, I have not noticed the unit being slow to any extent. Can you explain more on what you noticed? Truly enjoy the unit but a little high in price. Have you noticed anything else or any other comment? Joel, K2QBV*

Hi Joel

Are only few ours that I'm using the new RCU and I can say for the moment that is beautiful.Settings are not difficult if you get into device's philosopy. Nice the colored screen. I noticed that it is kinda slow in data processing, but is only a my idea, can you survive the same hihi.I'm familiar with the cw contest speed hihi.
I reserve other comments after using it in contest all band where you need a lot of bandwidth and antenna switches... I want to put it under tough pressure hihi. Best 73

This has been intermittant problem for just a bit. When I press the ON button on the RCU the unit starts to turn on and then goes off. Did this a couple of weeks ago and then it came on and operated for a weekend without any problems. I can hear a relay open and then close somewhere in the front panel area.

Sounds like a comm issue between your RCU and the controller.

I ran across that issue with a friend, he replaced the RCU as it was losing comms between the controller and the 2k.

I have a RCU you can try out to see if that cures the problem.

Thanks for the report John. It is on now. I don't know why this would ever have anything to do with it but I turned off my IC-7800 then turned on the Acom and it came on right away. Strange....

John,

I am the happy owner of an Acom 1500 which I purchased new in the fall of 2012. So, I haven't had it very long..

That being said, I really like the amp. It has excellent protection circuitry, puts out gobs of power and does so effortlessly.

I can't speak to long term use -- I probably have 30 or 40 hours on the amp, all CW / QSK. So far, excellent.

I chose the 1500 because I wanted to run full power, I like single tube designs and I couldn't afford the Acom 2000. ;-)

73,
Doug, W7KF

5335. Upgrade from Acom 1000 - 1500?

Topic: 5331 Message: 5335

I also have a 1500 and so far seems fine.
While I purchased her for 6 meters exclusively, she makes a nice backup to my ACOM 2000A; and thusfar has had some but little use on 6 meters. Being able to accommodate up to three antennas as a standard option is a nice advantage as well. She delivers about the same or even more power than the Alpha 6 I had plus has the added value of HF support as well, but much less than the SPE 2K-FA. The price/performance seems in line especially with the price increase on the ACOM 2000A and CAT RCU.

I don't understand the rationale for the ACOM 1500. It's significantly more expensive that the ACOM 1000 and doesn't really offer that much more. It's price slot puts it into competition with the Alpha 8410. Regardless of what anyone might think of Alpha generally, the 8410 seems to offer a lot.
The US distributor wasn't able to offer any clarity on the matter either. I suspect it may be a response to market "nervousness" about the availability of the GU74b.
Anyway, I purchased a used ACOM 1000 and I'm, so far, very pleased with the equipment.

The Acom 1000 is indeed a bargain.

The 1500 offers legal limit output in the same sized package which is very attractive for many - specifically 6m enthusiasts.

In addition, since it is about 10 years 'younger' than the 1000 it has some added features that are nice including support for 3 antennas.

From: myles
Topic: 5342 Message: 5342

was finally able to make a cable to hook the amp up to the Microham MKII.

Works fantastic, followed the manual to make the cable, and it has been tracking perfectly since. Lots of fun!

Thanks to all those that helped me w/some tips on there setups.

5343. Re: [acom-list] Acom 1000 drive level and RF power Gain

From: Trevor Dunne
Topic: 5099 Message: 5343

Hopefully someone might be able to help me,

I noticed during the RTTY test that on 10m I am only getting about 800w out, antenna has a 1.1:1 SWR

What I also notice is that the rig will not go above 50w drive when the amp is online if I put the amp into stby I get 100w through the amp.

When increasing the drive about 50w there is no indication of a SWR rise on the rig,

It is working ok on all the other HF bands.

Not sure what is going on

Thanks

Subject: Re: [acom-list] Acom 1000 drive level and RF power Gain

Just to update this as I didn't get much response the first time around,

I did a test on all bands and they are all ok with the exception of 10m.

on 10m If I am running 50w with the amp in STBY the meter on the amp shows 50w as it should,

If I bring the amp on line, I am only seeing 40w drive when it should be 50w as I have not touched the drive level on the rig,

I checked all other bands and the difference between STBY PWR and Drive PWR when amp is in line is maybe 1 or 2w, not the 10w that is showing on 10m, I notice the SWR will rise a small bit as well, would the circuit in the amp be out of tune on 10m or maybe some sort of issues with the tuner/coax switch, patch cables???
 That's why I have to push the Rig harder to get the same output on 10m,

It's not a issue I am to concerned about bit will monitor it to make sure it does not get any worse.

Thanks

Hi All

I notice that to get full output I have to use more power from my rig than before, usually around 60w was enough to get up to 1kw,

Now I nearly have to run it at full power to get that, its worse on 10m

The RF power Gain is only showing 12.0dB I am sure it used to show more,

I don't use the amp that much and its about 5 years old,

would the tube be getting weak ???

Thanks

Greetings Trevor,
Are you connecting the ALC line from the Amp to the rig?
Try disconnecting it and test.

Another possibility is, if you are comfortable working with covers open, please try to perform the
bias adjustment. EB1 and EB2 pre-sets. This is dangerous, but not if one knows what to do and
what not to do.

My amp showed about 855w on 20m, but when i checked the Bias, EB1 was
alright, but EB2 was slightly off. Once i adjusted that to the given range, boy, it
puts out a nice 1.15kw for the same input power.

5345. Valve gone soft maybe? ACOM 1000

Yahoo group: acom-list (2010 — 2016)
Date: 2013-02-13 08:41:47 UTC
From: Gordon
Topic: 5345 Message: 5345

Hi.

Just joined the group. I have had my Acom 1K for about 5 years now.

During the WPX RTTY contest on Sunday evening, my amp went faulty. On 40m, the ATT (attenuate) light flashed and cut the output to real low power. About 90 watts I think. Upon checking, I can now only run about an indicated 18w into the amp before it self protects. That is only good for about 170w output. As soon as I up the drive any higher, the ATT flashes and cuts the power.

I just tested all other bands and although the ATT doesn't cut in, I found the power output to be much lower than it used to be. Testing into a dummy load (of course), I found I was getting between 550w to 700w on everywhere else. Previously, the amp produced more than a Kw with about 50 - 60w drive. I don't use it at that level ever.

So, hopefully the valve has gone soft and any other fault hopefully?

Although I've noticed the lower power output for some time now, what worries me more is why it suddenly just seems to fault on 40m now?

Thanks for any help.

Gordon

From: Mel Whitten
Topic: 5346 Message: 5346

The local power company here had a "failure" and caused my 240vac to increase to nearly 300vac. Before I noticed this, it burned out the heaters on both tubes. I have spare tested tubes but they have not had their heaters on since I received them in Aug of 2008. Is there any conditioning I need to do with these other than let them warm up for few hours or ? before putting them into use?

Follow the bias adjustment procedure when you install them and they should
be just fine.

I'll email the procedure to you as well as post it here on the group file
area.

It would be wise to preheat the tubes before using them in an amplifier. Most GU74B manufacturer tubes are dated way in the past. Tubes older then 5 years are recommended to be preheated before applying.

Bruce,

Were you able to figure out what caused this? I'm doing the ARRL DX contest right now, and my rig is able to drive the 2000A to full power with only 20W output!

5359. ACOM 1000 goes in autoprotect during switching bandswitch

Yahoo group: acom-list (2010 — 2016)
Date: 2013-02-17 14:47:32 UTC
From: Ger
Topic: 5359 Message: 5359

Hi All,
My Acom 1000 developed a strange problem out of the blue.
Here is the situation: when Amp has been powered on after 3 min heating time and when I switch from 14 Mhz to 18-21 Mhz, its goes in auto-protect SB2B. Amp is still in standby (oper switch not engaged) When I engage the oper switch, I can switch bands without immediately going in SB2B auto-protect but after 2-3 switching it goes.In standby it immediately goes in auto-protect when changing the band switch. I tried this with en without PTT line connected: same results. Apart from this weird failure the Acom works fine on all bands:more then a 1 K output. Also I tried this when the Amp is still heating up and at the moment I switch the band switch, beng auto protect SB2B.
Anyone any idea where to look?

Thanks, Ger PE1CZG

I reseated the connector inside the RCU and all is well. Must have had some oxidation over the years..PHEW.
FYI, this connector can be plugged in either way, beware if you completely remove it.

5365. Acom 2000a "Screen voltage on before timeout over" - round #2

Yahoo group: acom-list (2010 — 2016)
Date: 2013-02-22 13:21:31 UTC
From: James
Topic: 5365 Message: 5365

Dear Acom 2000a experts,

Two independent amplifiers - one at a DXpedition location, and one at my house just produced the infamous "screen voltage on before timeout over" error message.

In the case of the DXpedition amplifier, it was one year since the amplifier was used, and it worked great one year ago, now boots up continiously with this error message.

In the case of the amplifier at MY house, it has been only one week since the amplifier was used, and it worked GREAT the last time it was used...now boots up continiously with this error.

I have read the limited information about this problem and it is almost always described as a potential tube problem.

One year ago (with a 3rd Acom 2000a - 1999 model) I posted a question about this error - couldn't figure out the answer so I sent the amplfier to Acom for repair and this is what they replaced:

(1) TRANSISTOR-2N3904
(1) IRF710-ND (not sure what this is)
(2) IC REGULATOR L7805CV
(1) ECST1VX225R CAP 2200 UF 16V TANT TE SERIES PCS6225CT-ND

Can anyone tell me if that capacitor referenced is the "infamous" C2 that I hear about routinely replacing? Where exactly is C2 located?

I cannot tell what was replaced - to fix the amp vs. what was replaced as a field upgrade.

I will, of course, try a new set of tubes in both broken amplifiers, however I am curious to learn what other "off the shelf" solutions have been discovered for the "screen voltage on before timeout over" error message.

Thanks in advance for any help and guidance.

73,

Jim Nitzberg WX3B

5366. Acom 2000a "low gain" error

Yahoo group: acom-list (2010 — 2016)
Date: 2013-02-22 16:58:45 UTC
From: Ron W3ZV
Topic: 5366 Message: 5366

I am attempting to help a friend rectify a problem with his amplifier. The problem is frequency specific and only occurs on the bottom 50 KHz of 80m. My friend is a 100% CW op and I am willing to bet that he never operates out of the bottom 50 KHz of any band.

His current operating lineup is an FT1000, Acom-2000a, MFJ high power manual tuner and a G5RV. As far as my limited testing goes, the amp operates normally all bands except 80m when operated into a dummy load. The amp operates normally from 3.551MHz through 4.000MHz

In the bottom 50KHz, the amp faults with a Low Gain error and goes into standby. My reading of the manual leads me to believe this is somehow related to the amp's tuner and stored tuning solutions. The method of clearing this error and the difference between DEF and USR in this instance are not immediately clear to me.

1. How do I redo the tuning to clear this error?

2. Is it possible and/or advisable to disable the amp's tuner and user the wider range external tuner?

Thanks in advance.

Ron, why not simply retune the amp using the auto tune steps described in the manual. It may simply be out of tune, or perhaps never tuned in the first place.

That's the best suggestion - re-do the user tuning in that segment.

Also, to clear up a popular misconception, the amplifier does not have a "tuner" in the sense of an antenna tuner - this is simply the normal tank circuit of the amplifier (tune & load capacitors and a switched inductor) so it cannot be disabled.

You certainly can use the external tuner to make the SWR appear better to the amplifier which would make it tune more easily.

The G5RV is notorious for "RF in the shack problems" but this doesn't sound like one of those cases.

> Thanks in advance
> Mark
> M0UTD

You are sending RF into the Acom before it's relay has switched.
It's fast to switch, but not as fast as some solid state radios.

You need to add delay in those modes, don't know the rig so perhaps check the menus for some delay options.

Hola Ivan !

My guess is you have at least one defective final amplifier tube, perhaps a component as well, but likely just 1-2 tubes.
If you Google around "ACOM 2000A Bias Too Low", you will find that to be a likely scenario:

5374. Re: BIAS TOO LOW AT POWER ON: -044V

Yahoo group: acom-list (2010 — 2016)
Date: 2013-02-23 21:38:52 UTC
From: Jay Terleski
Topic: 5369 Message: 5374

This problem can be cause by several component failures. I don't have the schematics with me right now, but check.

Zener diode string for the -127V regulation. Some of these may be shorted.

Bias supply diode bridge for shorted or open diodes.

Bias supply electrolytic caps and the cap at the zener string which can go bad.
The bias supply cap can allow huge ripple which will look like low bias error you see.

Hope that helps.
Jay

There is no "optimal" temperature. You should run the amp at no more than 1000 w output, and depending on your environment and how much you transmit, the temperature will vary a bit.

What causes you to ask this question? The amplifier monitors its own temperature so you don't have to.

"SB2B" indicates output relay closed during standby. I'm guessing that the influence of the band switch is mechanical.

I would replace the output relay.

> Here is the situation: when Amp has been powered on after 3 min heating time and when I switch from 14 Mhz to 18-21 Mhz, its goes in auto-protect SB2B. Amp is still in standby (oper switch not engaged) When I engage the oper switch, I can switch bands without immediately going in SB2B auto-protect but after 2-3 switching it goes.In standby it immediately goes in auto-protect when changing the band switch. I tried this with en without PTT line connected: same results. Apart from this weird failure the Acom works fine on all bands:more then a 1 K output. Also I tried this when the Amp is still heating up and at the moment I switch the band switch, beng auto protect SB2B.

Hi Bob, thanks for the response. I see the book says you can operate at full power rtty with like 15 mins on with 3 mins off time without adding the optional fan. My running without being close to full power, the temps shoot way up in comparision to the SSB & CW modes which is expected. So I just looking at what maybe considered a safe level of operation in RTTY by the exhaust temp.

Hi Randy,

As Bob says, the cooling takes care of itself (via a variable speed fan.) If you are looking for absolute values, my ACOM-1000 idles around 38-40?C. Under heavy use I've seen it at 80-85?C for short times. As soon as you stop transmitting, because the fan is going quite fast, my temperature drops down to the 38-40?C range in 60-80 seconds.

These numbers and the rate of drop can vary for several reasons. These include the ambient temperature in the shack, circulation around the amp, etc. Keeping the rear dust filter clean can cause these numbers to vary by 5?C or more. I think what Bob is saying is that regardless of the absolute numbers, you can be confident ACOM's sensors coupled with the variable speed fan will keep the tube well within the temperature specifications.

Bottom line -- don't be concerned about exact numbers. Find your idle and max transmit temperatures and note them. They should stay fairly constant within your range. If something goes really wrong, they will change a lot and you'll need to investigate why.

It's also a good idea to vacuum your fan filter on the rear about once a month.

Date: 2013-03-03 11:33:31 UTC
From: g3xrj
Topic: 5383 Message: 5383

Amp was idling and 30mins after last QSO - went to fault condition flashing red power light.
Auto Protection PR06
Fault codes
1APR06 000500 000039
1BA49A 67s0DC D77F95

Did the simple thing first and changed the tube.
Same fault codes produced.

Checked Bias during warmup and voltage at R16 is -116v

I had previously checked the bias volts at R16 during normal operation and found them to be -157 key up and -134 key down.
I checked this because during the last two years I've had to adjust the bias volts to bring the Plate current within spec. on three occasions.

Questions I have
1. Should the bias volts at R16 be normal ie -157v during warmup.
2. If normal bias volts are not available during warmup - how should I proceed.
Any pointers please.

John G3XRJ

Hello

I am having the ''heater light"" come on blinks frequently, (ACOM 2000A AMP) not constant, but blinks. The issue I believe is the INCOMING MAINS VOLTAGE. We here in the island of Grand Cayman have very poor electrical regulation of voltage. When I checked the ''MAINS VOLTAGE'' when the ""heater lite"" comes on it is running 256V.. !!, Anyway the electric Company is reluctant to do much about it

***WILL IT HURT THE AMPLIFIER?
***WHAT CAN I DO TO STOP THIS?

help!!! ACOM?

*Regarding your ACOM 2000A.....Allow me to give you what I believe to be the correct solution. First off, check the line voltage and compare it to the RCU voltage indicators on the display. Sometmes the PR13 pot in the Acom 2000 is not set correctly and the heater lite comes on. This voltage must reflect how the pot is set up. The heater indicator lite will not hurt the amplifier as it's not wired up to any default circuit. Second thing you may want to look at in your Acom manual is setting the input voltage to the proper position next to the transformer. Joel, K2QBV *

256 VAC is a bit high, but you might want to measure it with a known good meter before jumping to conclusions. The voltage measurement circuit in my 2000A drifted over a period of years, and I saw excessive mains voltage and the heater light blinking, but after a recalibration at Array Solutions, the problem stopped.

If you're sure the mains voltage is really too high, you should keep an eye on the filament voltage since it's the only one that can significantly shorten tube life. It should not be less than 11.9 V or more than 13.3 V. Here is a link to the factory specs on the GU74b:

Joe,

The amplifier is able to operate with higher line voltage like you have and the blinking indicates that you're getting close to the upper limit - and you are. The upper limit (by design) is 264v (+ 10%).

You should be on the highest transformer tap, which is the 240v tap.

Also, in the manual, it describes how you can adjust the amplifier's monitoring circuit to accommodate this through the "OFF" Menu:

<Begin Manual Quote>

5-6. DEF (Defaults)

In this sub-menu you can vary the operating mode of the amplifier to cope with abnormal mains voltage, set the local network self address of the amplifier, and change the antenna selection mode. Once DEF has been selected, the 3 sub-menus are reached sequentially by pressing "ENT" to step through them.
a) After selecting DEF, the first time you press the "ENT" button you will access the MAINS VOLTAGE function:

MAINS VOLTAGE
LOW [NORMAL] HIGH

N O T E: Inappropriate use of this function may reduce the gain or the maximum undistorted output power.

At constantly lower or higher mains voltage you can declare this to the amplifier. The information is taken into account for the preparation of the next USR-tunings. Selection is done by the "<" and ">" buttons. Pressing the "ENT" button confirms the choice selected, while "ESC" preserves the previous parameter.

<End Manual Quote>

The "OFF" Menu is accessible while the Main switch on the amplifier chassis is on and the RCU is "dark" or when you have not yet pressed the red "ON OFF" button on the RCU yet to begin the warm-up period.

I left something out of my last posting concerning the Acom 2000A. The amplifier will reset at 258 volts as a safety and that number is the top limit. Again, the RP13 setting is a very small pot located on the vertical board facing the front and right near the little memory battery. Setting this pot will get rid of the flashing heater lite.....Good luck with the unit.....Joel, K2QBV

5392. Acom 1000: 4.7V Zener on HV Board

Yahoo group: acom-list (2010 — 2016)
Date: 2013-03-06 12:43:04 UTC
From: Dean
Topic: 5392 Message: 5392

My Acom 1000 has been coming on with a PN07 fault which is an indication of the absence of HV (as measured). After some troubleshooting, I suspect that a defective Zener diode may be causing the problem in the metering (HVi) circuitry.

Having tried to find a replacement diode on island, I can only find a replacement rated for 0.5W while the diode is rated for 1.2W.

Can anyone say whether it would make any sense replacing this diode with the smaller one? I would normally not even ask but am hoping that I might be able to get away with it even for a short while to determine that this solves the problem or whether I might have a transformer problem.

Essentially the PN07 error comes on and the 2 slow blow fuses in the step/start circuit are blown on power up. initially I thought it might just have been the fuses, but they blew when replaced leading me to look at D6 on the HV circuit.

Any help or comments would be appreciated. Shipping the unit back to Acom is always an expensive undertaking from 8P.

Regards,

Dean - 8P6SH

Dean,
I lost the 4.7V zener last year in the HV voltage sampling circuit. However it does not cause fuses to blow. I suggest you email Acom Bulgaria (Stan), they will help you find the cause. Please advise the group what the issue was when its resolved. I hope its not the HV transformer as whilst its not hard to replace its very expensive.

Thanks for your input. The unit is under warranty, so I have sent it off today to Array Solutions. They suggested that I check a few resistors which checked out fine. I am using the new RCU. I hooked up the older style RCU and got a similar error message, but the voltage given was 410 or 430V rather that the 60V stated by the newer RCU. I want them to check the CAT in the new RCU since I am getting a lot of band hopping using the CVI connection with my ICOM 7700.

5398. Re: G2 voltage too high error & CI-V problem

Yahoo group: acom-list (2010 — 2016)
Date: 2013-03-07 21:55:22 UTC
From: Ralph
Topic: 5393 Message: 5398

Jeff,
If you have the 7700, 2000A & PC hooked up on same CI-V, all in parallel such as with CT-17, that is the cause of your band hoping. One thing you can try is to remove the connection to Pin 3 on the new RCU DB-15 connector. That will stop the 2000A from polling the 7700. Just the logging program should poll. The real cure is the Microham units that have the separate dedicated CI-V output, originally for the PW-1 but works with most computer connected amps including the 2000A. But it is still advised to not connect that Pin 3 on the new RCU DB-15. Also with the Microham you do not need the two resistors per the ACOM diagram.
Been through it with Val at ACOM.

Thanks Steve

I took your advice and so far making some progress. Acom Bulgaria advised me to disconnect the 340V and 120V supply from the main board - JP2 and it started up OK - which means the fault is in either of these circuits.

When I measure the resistance across these terminals JP2:1 &3 and JP2:6 & 8 - from your knowledge of the circuitry - surely i should get an open circuit reading? The capicitors C28 and C18 are basically across these terminals along with the full wave rectifiers for the 120 and 305V supply circuit (Grid and bias I think) - Instead on the circuit I get a realatively high 1.5M ohm resistance which increases rapidly to open circuit reading.

So I believe I have some kind of leaky capacitor across the 305V supply - nut am not sure how this would translate into a HV problem.

When I disconnected JP2, the amp started up and went through its countdown sequence. Naturally I would not have transmitted as the tube did not have bias or grid voltages.

Any thoughts?? I am just being impatient as I am awaiting a response from Acom on my strange resistance readings. I guess Acom will respond on Monday.

I am also very suspicious that the first set of slow blow fuses were not genuine slow blow fuses as well which may have caused them to blow again.

Originally I had the amp on for the week-end of some contest and left it idling to bring the tube temp down before turning off. I ended up with it unattended for a while and when I returned it had this PN07 error. When I physically checked, the fuses were blown so changed them with this set that looked like normal but the packaging said slow blow - purchased from an electrical hardware store while the current ones are from an electronics store. Maybe I should just fire it up again...

Regards and 73's

Dean,

On the contrary, the ohmmeter readings you quote indicates that the capacitors are probably good.

Here's the scenerio: When the cap is fully discharged and you apply a voltage to it, it draws a large current while trying to charge. To the ohmmeter this looks like a low resistance. At full charge, it is not drawing any current thus looks infinite to a voltmeter.

So look beyond the caps for the problem.

I'd have to look at the circuit diagram to see why the reading starts at 1.5 meg. There may be some kind of series resistor in the circuit.

Thanks Brian

Good point. Makes sense to me. I get quite edgy anytime I open up an amp so anything is possible but thanks for your input. That's consistent with known good HV circuit which i've subjected to similar tests. Seems to me all the three PS circuits (2050V, 120V and 305V exhibit similar behavior.. albeit with slightly different specific numbers. All the diodes too (tested in circuit) appear to be fine.

Oh well I'll just wait and see what Acom suggests. I'm very suspicious of those first set of replacement Slow blow fuses though. Hopefully the only original issue was a pair of blown fuses maybe a bit of a surge or something, followed by their replacement with suspected fast-blow fuses, being sold as slow-blow which of course blew immediately.

Fingers crossed.

Regards,

Dean - 8P6SH

Sent: Tuesday, 12 March 2013 10:02 AM
To: acom-list@yahoogroups.com
Subject: [acom-list] Selling my Acom

Selling my Acom 1000 4 months old with maybe 2 hrs of talk time.
Decided to go with a PW1 to match my Icom equipment.
This amp is in like new condition with all original manual and
Box and packing. They are great amps .

$2700 shipped.

Steve

I mean no offense, Steve, but what is yourcall sign? It is always fun
to see if I have worked someone who posts on some of the same lists I am
on, but more to the immediate issue it gives all of us some insight into
what half of the shipping charges might amount to.

5410. Spring Cleaning

Yahoo group: acom-list (2010 — 2016)
Date: 2013-03-21 14:39:09 UTC
From: kamarty456
Topic: 5410 Message: 5410

For all you owners of ACOM amplifiers and for all the
2000A users...

This is a reminder to clean your air filter!

This is a task we often forget.

To keep your ACOM happy you must clean your filter!!!!!

In Arizona we have dust..lots of dust so I clean my
filters [yes two] every 3-4 months.

I have the external muffin fan and use a metal pre-filter
screen in addition to the foam filter.

I last opened my amplifier when I did the EBS bias modification
and noted NO dirt or dust bunnies!

The filters do keep the insides clean but if clogged with dirt
you will indeed develop air flow challenges and rising temperatures.

So wash the filter NOW! You'll thank me later.

My 2000A is almost 12 years old and runs perfectly.

Martin KA7GKN

5411. Acom 2000A For Sale (UK)

Yahoo group: acom-list (2010 — 2016)
Date: 2013-03-25 22:09:41 UTC
From: g4obk
Topic: 5411 Message: 5411

Having given up DX work and contesting other than taking part in RSGB Low Power events and SOTA, my Acom 2000A is for sale. I no longer need Acom power.

This linear has had little use for the last 3 years but still performs as it should.

Purchased in December 2004 by me - brand new from Vine Antennas.

There is one small 5mm long fine scratch on the right side of the case -otherwise the linear and its controller look like new.

Buyer must collect (North Yorks - 30 mins drive from York) or pay my fuel cost of delivery (within 150 miles max of my QTH only).

Would consider P/X for a lower powered solid state amp or will sell for £3300 ONO. If you are interested please reply via e-mail.

5412. Acom 1000 slowly producing power

Yahoo group: acom-list (2010 — 2016)
Date: 2013-03-27 18:28:36 UTC
From: Paul P
Topic: 5412 Message: 5412

Hello all

My Acom 1000 has developed a strange fault,not really sure what to think about it.

When the amp is first switched on and keyed no power comes out of it,then slowly the power appears as the bargraph slowly creeps up.

It never reaches the heights it used to but it still runs about 70% of the previous power.

There are no alarms,no shutdowns,the SWR on the antenna is fine,Ive replaced the drive patch lead and also the rig just in case,but its still the same.

It seems to work alright,but if its flicked to standby and then flicked back on it starts with no output power again,and slowly the bargraph creeps up to about 70% of previous power.
The only thing I have not done so far is put an external meter on it to see if what the bargraph says is happening..is actually whats happening.

I just wondered if anyone else had had this problem before I launch into the inside of the amp.

Regards

Paul G4RRA

I was thinking along similar lines Paul

I do have a couple of tubes I could use to test this theory,they currently reside in my 144Mhz amplifier, so I might just borrow one to confirm this is the case.

Or I might just buy another tube as I dont have a spare !

I never saw this behavior with a soft tube. What about the Anode Current? Is this also slowly increasing? What is the gain: should be between 12-13 dB. When all of these parameters are ok (not creeping up with the power on the graph) I recommend to use an external power meter first. I know from personal experience that a lot can go wrong with the perimeter electronics of the Acom 1000.

5419. Which rigs have been proven to not have an ALC Spike?

Yahoo group: acom-list (2010 — 2016)

I am in the market for a new ham radio but I see lots of new rigs with the ALC overshoot. Can anyone chime in and tell me how their rig works with the Acom 1000?

Thanks, Sonny....AB4VV

3 radios that I had /have have no alc overshoot with my Acom 1000
Icom 7600
Tentec omni7
Tentec Eagle.
Overshoot occurs with Icom7200.
Goodluck 73's David N4DOV.

Worst ever was the IC-775. At 100W setting it would spike to 350W.

All Yaesu's seem okay.

It's mostly Icom radios. Don't buy an old IC-781.

Correct, I had an IC-775DSP for a couple of years. The power spikes were terrible! The IC-7700 which I owned for 2,5 years had not.

Some Kenwood rigs suffer power spikes (and ALC problems).

For what I know no power spikes have the FT-1000D, FT-1000MkV's, FTdx5000. I don't know/heard/read of any Yeasu rig with this power problem.

The Acom2000A is very sensitive for power spikes. The old ETO/Alpha 91b is not.

73, Hans.

To add to the confusion, I don't use ALC, but the Icom 7600 has a key up spike. I have an Icom 2KA it doesn't like radios with keying spikes.

I use a 7600 with an Acom 2000A or a solid State Elecraft KPA-500 and do not notice any keying spike. Serial number is above 29xx.

Never an issue with this rig.

73 de KE4WY Jim

I have an Acom 2000 and never had spiking issues with my Pro3 or FT847 yet the Flex5000a was horrible causing ARC faults. Finally after almost a year, Flex fixed it with a software change adding a "slew" check box that fixed the problem. The other temporary fix was a hi-pass filter ahead of the Acom input. Apparently the FLex has some strong artifacts or spurs below 1mhz causing the Acom to fault. A simple hi pass filter that cuts off at 1mhz worked fairly well. I doubt that this is common to all the rigs that spike. Krassy of Acom got involved and if I recall he was going to do something on the input. You might contact Acom if you haven't already.

Acom 2000 plus FT1000Mp mark V Field here and no problem at all.
I do have another combo FT897D and Expert 1K-FA and yes, it did have some power spikes...Hardly often but happens.

Funny, that is the exact same problem that was encountered with the Ten-Tec
Orion back in 2004. There was low level low freq artifacts tripping the
Arc Fault circuit. Ten-Tec offered a high pass filter to fix the problem
to anyone who complained about it.

5432. ACOM 2000A amplifier

Yahoo group: acom-list (2010 — 2016)
Date: 2013-03-30 20:34:00 UTC
From: Joel Kornreich
Topic: 5432 Message: 5432

With all the chatter around, here is my experience using the Acom 2000A with the FT2000D......When I first purchased the FT2000, it was the new "D' model (FT2000D) that Yaesu had produced along with the run of the standard FT2000 units. The FT2000D had a "forward spike" that always, 100 percent of the time put the ACOM 2000 into a reset mode. It did not matter what the internal output was set for or even if the RF POWER switch was near or at zero, the amplifier would reset. Since the "D" model was new to Yaesu, it made four trips back to California for repair. The repair group in Cypress California could not determine what or where the problem was. The FT2000D was sent back to Japan to the engineering group and modifications were made in California before new units were released. The point of this tail is determine if you are buying a used radio, find out if the FT2000D you are looking at had been modified. To find out about the mod is to put the rf output on a good scope and the spike will show up. Units purchased over the last two years from Yaesu have had the changes made in manufacturing. Good luck, Joel, K2QBV

I use the acom 1010 amp with my 7800 and it works flawlessly no issues ever. both work really well together.

See my setup on QRZ and youtube.

Are some generations of the 2000A more susceptible to this than others?

Mel,

You are in the majority who did not have this spike problem. Flex PwrSdr 1.xx did not have the problem for me or anyone else but version 2.xx did. Because the Acom Arc fault implies you have a transmission line problem and I was the only one complaining they were convinced it wasn't the radio. Gerald, Flex owner was excellent working with me but it took months to convince him it was their software and when another ham in ND mentioned he had the same issue they finally fixed it with the "slew" option check box. My spike was not "forward keying" as Joel mentioned with his Ft2000 but was "reverse or key release" that caused the spike. 10w of power out of flex into amp would drop the amp every time. The hi pass filter was tried based on an HB9?? who made a simple hi-pass filter suggesting it might help and indeed it did allowing me to get almost 1kw out but over that the Acom would again fault on key release. I think it was in 2.23 that it got fixed. I have had an early Flex 1000 they could not get it working for me and returned all my money. I had a Flex 3000 and that worked well and dollar for dollar was the best buy. I then bought a Flex 5000a and finally got tired of all the PwrSdr issues with upgrading, the spurs and images, harsh and raspy audio now finally fixed, never made the 60w on v/u as advertised and finals that would fail which I did not encounter but others did. I now have no Flex radios and own an Apache-Labs Anan-10 (can receive 5 bands without another RX installed) awaiting for the new Anan -100d (can receive 15 bands, diversity RX, TX beams steering and more) to be delivered. It runs with an improved PwrSdr so no learning curve and half the price of the Flex. Many of my friends have the Flex radios and love them and hope Flex 6700 can get up and running for comparison. So far they have not been able to demo it.

I have had the Acom 2000a since 2001 and love it. Best amp on the market as far as I am concerned.
Beside having to replace the tubes after a low bias reading, I had one other interesting problem. The Acom would not power up with nothing shown on the RCU. I brought it to Acom in MA and they worked on it for a few hours to find out I had reversed the plug going into the RCU PC board when I was tbl shooting. Beware, it can go in either way as there is no key. This was years ago and just last month the Acom would not power up again. I simply reseated that connector and all is well. Good one to remember.

73's
Steve

The Flex radios work FB with the Acom2000A using current PowerSDR software. I have not had to use any additional filtering.

Funny, that is the exact same problem that was encountered with the Ten-Tec
Orion back in 2004. There was low level low freq artifacts tripping the
Arc Fault circuit. Ten-Tec offered a high pass filter to fix the problem
to anyone who complained about it.

HI Neal,

Long time no chat, PC's are working good and guess we both are waiting for our 100d.
Your question is a good one which I have no definitive answer except mine was one of the first and a friend has the very first one and unlike me, has had no spiking issues with his Flex 5000 and Acom. If I recall the Tokyo amps were one of the first to have spiking issues. I believe the problem is with the Transceivers and not the amps. I think the transceivers are putting out full power and a few cycles later reduce it to the proper or set power. I wonder if the transceivers could put on power first than key up milliseconds later if that would help, sounds too easy. If you notice in the W5WC PwrSdr transmit section this is addressed with separate MOX and RF delay options.
Maybe Array Solutions can get this answered.

Actually, if it's a forward spike generated by a transceiver the answer is no. The fault circuit will shut the unit down as it's designed with protection in mind. If it does not go into a fault mode something may be wrong with the Acom....Joel, K2QBV

It should also be pointed out that some rigs that produce the leading
edge spike can be adjusted to minimize it.

Hi all,
My recomendation is to use only KEY-IN.Don?t use KEY-OUT neither ALC. Even Acom recomends not to use ALC.
With just one conection from Yaesu TX to Acom KEY-IN works perfect.
It is how it works for me with FT-1000 or FT Dx-9000 and Acom 2000A.

From: sv1qot
Topic: 5444 Message: 5444

Hello dear friends,
As i mention in the subject i own an acom 1000 and a yaesu ft-950.
My problem is that when i find a dx qso with split frequency the tranceiver in tx have high swr and of course the amplifier cant transmit.
If i put the antenna straight in transceiver everything is ok.
Does anyone have anything in mind.
A solution ???

Is the amplifier and radio working correctly when non split?
Try to adjust the amp in the Tx freq, then activate split.

Maximo hahahaha,good morning from Greece,
As you realize im new in linear amplifiers.
So im so stupid i was adjust the receiving frequency but not the transmitting.
So the transceiver see not 50ohm in his rf output.
So simple.
Thank you very much Maximo.

5447. Troubleshooting low gain, 2000A?

Yahoo group: acom-list (2010 — 2016)
Date: 2013-04-07 19:39:51 UTC
From: N1EU
Topic: 5447 Message: 5447

I'd appreciate troubleshooting tips for low gain on my 2000A that started suddenly yesterday. The basic symptom is low power output with the amp other appearing to operate normally. But on closer look, the gain seems to fall off steadily and dramatically with higher frequency and a "Low Gain" fault will appear on 12M and 10M.

The manual just says to rerun Auto-Tune which doesn't help. Anybody been here before or have any suggestions?

Thanks & 73,
Barry N1EU

Hi Barry..
how many hours do you have on your tubes?
Also have you tried testing using a dummy load?

What are your parameters? High voltage, line voltage..etc

Tubes are relatively new - a few years of light use. Same symptoms on
multiple antennas. Parameters look normal, except gain.

I checked the bias current and the high level idle current seems low (220ma vs 375ma spec) so I'm going to try and adjust that and see if it makes a difference.

If not and other advice comes forth, I'll swap the tubes in the next day or two and see if that helps.

From: D G
Topic: 5447 Message: 5452

Some folks have had a "Bias Too Low" error and it was tubes or a component like a capacitor (Google will help find the string). http://groups.yahoo.com/group/acom-list/message/5141 Maybe if you have not yet received the error on the RCU, it may be just starting, on the higher bands (just a possible guess). Regardless, this was the tube replacement process if you have a spare pair: http://groups.yahoo.com/group/acom-list/message/2757 73, DennisN3DG

Hi Barry,

Ordinarily I would say you have a tube aging out, but for it to happen very suddenly is not typical of a tube issue, although with everything else normal it certainly could be. How many hours on the tubes? Also, if this is a very early serial number, check the current into each filament....

Measure output with a watt-meter. Its possible one of the diodes that rectifies the output to determine forward power, and is used to calculate gain, has let go. A simple fix. The diodes are transformer coupled right on the output. Nearby lightning strikes and other impulses can take them out - although they are nowhere near as sensitive as on the Alpha 99, the RF deck of which is "the same."

Low idle current sounds like a tube. Meanwhile, I have cycled about a
dozen pair in and out of my two 2000As and I have never been able adjust
any of them up to 325 ma. in either amp....from memory I think the best
I ever got to was 275 ma. The pots are all the way up in both amps...

Thanks Brian, could be,

Now it's suddenly behaving a bit better: 11dB gain on 10-20M, although
still way under par. When I get a chance, I'll try a new set of tubes.

From: N1EU
Topic: 5447 Message: 5459

The factory suggested that I erase the memory (holding ESC key while turning the main amp switch on). This in fact seems to have fixed the low gain problem. Since all the memory was erased, I need to set the tuning for all the band segments I use. Now I'm dealing with Auto-Tune complaints of "Check VSWR Please Remove Drive" even though the Acom Measure indicates very low SWR. Manual Tune works fine.

Anyhow, I'm back up and running although I'd like to sort out the Auto-Tune issue.

5460. acom 2000a gain

Yahoo group: acom-list (2010 — 2016)
Date: 2013-04-10 17:49:51 UTC
From: Kenneth
Topic: 5460 Message: 5460

Here are my gain figures, measured on the control unit:
15.5 on 14 MHz and 21 MHz, and 16 on all other bands.
Is that about right?
Ken K5WK

5461. Wanted Acom 1011 - any condition

Yahoo group: acom-list (2010 — 2016)

Hello all,
Looking for a 1011 amplifier. Prefer working but will also consider in non-working condition, without tubes etc. as long as condition is accurately stated and price reflects condition. 1010 also considered. Both US and EU shipping address available. Let me know what you have.

Thanks for the offer, I'm interested, I want to see first if I can get any offers from EU, (shipping from US to EU will add significantly to the cost)

The reason why I prefer a 1011. I have a 2 meter amp using 2x 4cx250 with separate supply, the plan is to power the 2m deck from the acom and save some room, get rid of the bulky supply I have for the 2 meter amp. So the idea is 2 amps, same type of tubes, same parameters, one supply. I suspect Ua is the same in both 1010 and 1011 but I don't know about Ug2. Also other aspects like current monitoring, I would be more confident starting this project from an amp configured for 2 tubes. I plan to install vacuum relays for HV supply and screen, switch the control signals to and from the other box, finally to have an additional switch on the panel to be able to switch from HF to VHF. So it would be a pity to do that to a pristine unit under warranty, I would rather hack one that's beyond any warranty! A good supply is essential.

Just to keep you all up to date with my Acom that slowly produces power.

It seems I have now cured it,I replaced the valve and the fault has vanished..its also back up to full power.

Does anyone know what the standing current is supposed to be ? With no drive applied and the amp in operate mine reads 20milliamps which I suspect might be a little bit low..

Connect a dummy load (or an antenna) to the output. Install all
cables to the exciter as usually. Now, feed mains voltage, turn on
the amplifier and let the tube at least 15 minutes in STANDBY mode.
Please guard the accessible HV parts during this period!

Select same bands (preferably lower) on both the amplifier and the exciter.

Use a small-size, flat-tip, insulated screwdriver for next
adjustments. On the MAINS PCB, find the two trimmer potentiometers
RP1 and RP2 (marked "BIAS1" and "BIAS2"). They control the idling
(zero-signal) plate current of the tubes for low- and high- RF-drive
levels respectively.

Please note that RP2 will affect both idling levels, while RP1 - only
the low level. That is why, the high level is adjusted the first, and
only then is set the low level (according to the procedure described below).

b) Select the "Plate Current" information screen on the LCD. Go to
the OPER mode. Apply very small drive power in CW mode (1...5W).
Following the plate current, adjust R2 (BIAS2) to reach 220mA
(200...240 is OK); CCW rotation will increase the current. Don't
exceed 15 seconds with the PTT on. If you need more, repeat the
adjustment 1-2 minutes later.

c) Do not apply any drive during the adjustment of R1 (BIAS1). Select
SSB mode, with the MIC and OUTPUT regulators on the exciter set to minimum.

While monitoring the plate current, adjust R1 (BIAS1) to set the
plate current to 70mA (60...80 is OK); CW rotation will increase the
current. This adjustment does not affect the previous step.

Thanks Uffe..I did just that yesterday and this morning tried to set the bias with those parameters and just could not reach the levels required.

last night the same problem occurred as last time,the power slowly coming up.ttogether with low power output so it's plainly a bias issue and not the valve..so at least I now know where the problem lies.

I will have a closer look today to see if I can work out what the problem is...I can't remember if there's a schematic in the back of the manual or not.

Thanks Paul

Hi Paul,

If not there is a detailed schematic in the "acom1000_doc.zip" in the Files section.

Personally I do not like the dynamic biasing, so I disabled it by short-circuiting R11 on the MAINS PCB, and re-adjusting the bias setting (RP2) to around 120 - 150 mA.

Who knows, that might fix your problem as well, although it sounds the G1 supply is having some kind of problem.

Hi all

I am thinking about buying the ACOM 1500 at Dayton. Owners of the ACOM 1500
I have a few questions.

How is the linear?

Any problems on any of the bands 160m to 6m?

How far have you pushed the power to?

Thanks in advance.

Topic: 5471 Message: 5472

Hi John, have the ACOM 1500 dedicated to 6 meters and a backup on HF to the ACOM 2000A.
It's a great amp, although I rarely use it as 6 is rarely open.
It will safely deliver 1500 Watts which was what my Alpha 6 did, maybe a bit more, but the power supply is not as hefty as the ACOM 2000A so I would not push it that far.

Jay and Bob at Array Solutions do a great job in support, give it a go (no reason to wait for Dayton, you can buzz or email them for your order as they're shipping) !!!

73 and enjoy !

John,

I have a 1500 that I got last fall, just in time for CW SS. (Got a clean sweep using it!)

I use it on 160 - 10 meters and have no issues with it. No antenna for 6 meters yet. It'll put out 1.5 KW but I typically run 1.3 KW or so.

It's easy to tune, the QSK is great, it's relatively quiet. I don't think about it much -- it just works!

HI Doug,

Thank's for your post.

I have an ACOM 1000 and the power is about 1KW with no problem.

So is the power of the ACOM 1500 really about 1.5 KW ? Because in France a good friend give me 1.2 KW with his 1500... so the difference is not too high to change my 1000 by a 1500 ;-(

Any one have some precision of measure ?

Best 73's and DX

5475. ACOM 2000a Remote Operation

Yahoo group: acom-list (2010 — 2016)

From: rcariello@...
Topic: 5475 Message: 5475

Dose anyone know what the maximum length the controller cable can be?
I would like to locate my 2000a within the room where I keep all my antenna relays. The control cable length from the 2000a and my 1000mp where I would keep the 2000a controller is about 130 feet. My thought is to simply wire up a cable with two DB9 connectors plug it in and see what happens. I am hoping someone has some information they are willing to share before I start this project.
Thanks for your help,
Rich AA2MF

Hi Rich,

As far as I can read on the Acom manual, maximum lenght are three meters/9 ft for the remote control.
Not sure if you can use some kind of serial signal amplifier or repeter to extend that longer.

Francis,

The difference between 1,000 watts and 1,500 watts is 1.76 DB. An S-Unit is typically 6 DB. So, jumping from 1,000 to 1,500 watts gets you about 1/3 of an S-Unit difference at the far end of the QSO.

I wanted the 6 meter capability of the ACOM-1500. If that had not been an issue I would have probably been able to find two used ACOM-1000 amps for about the same money. Then I would have had a spare amp!

I measure my output power with the ACOM-1500's internal meter and on an ancient Drake power meter. The two are in agreement that I can get 1500 watts out of the amp. But, as I said, I normally run at 1.3 KW or so. I'd rather get long tube life than the extra 200 watts (0.62 DB).

You could get that much gain by replacing RG-8 coax with LMR-600!

Loss at 30 MHz for a 33 meter length of coax:

RG-8 1.042 DB
LMR-600 0.421 DB
==========
0.621 DB Gain

Francis

I have an A1000 and when you look at the A1500 it is essentially the same basic electronics with a beefier power supply and different tube. I agree with Doug that there's not much difference between the 1k and 1.5k outputs.

In fact, when my A1000 was first in operation, I could get 1.2K easily on 40 and 80m but after maybe 5 years it runs closer to 1K as the tube has aged.

Personally I would not sell one to get the other but if I was looking for a new amp, I'd consider the A1500 for the higher output, better display, more robust power supply for my RTTY contests and more robust tube. I'd still run it around 1KW output but I'd feel a whole lot better knowing the safety factor.

In my view it is not in the league of the A2000 or Alpha 9500, 89's, 99's, 91B's etc. and doesn't have that "brick on the key forever" 1.5KW loafing ability. Instead I think it's fully 1.5K on SSB and 1.2K for RTTY and other high-duty modes.

To John's original question - While I do not own an A1500, I'd buy one in a heart-beat because its based on the electronics of a tried and proven performer in the A1000 with a solid tube, great display and quick and repeatable tuning system. i personally do not like amps with the multiple antenna outputs because I use external switching for 2 rigs so this is just another thing that could go wrong.

Regards,

Dean - 8P6SH

5480. Re: ACOM 2000a Remote Operation

Yahoo group: acom-list (2010 — 2016)
Date: 2013-04-21 17:00:57 UTC
From: Dick Green WC1M
Topic: 5475 Message: 5480

As long as you're very careful to get the pin connections correct and don't short any of them, I don't' think there would be any harm in trying a 130-foot cable run. But I'm not 100% sure about that.

Also, I'm somewhat dubious about it working.

Unlike the RS-232 computer interface, the RCU interface appears to be TTL, which runs at +5VDC/0V rather than the RS-232 standard +15V/-15V (or thereabouts). Also unlike the RS-232 interface, the signals don't go through a level converter / line driver. The signals between the RCU and 2000A are buffered and have transistor drivers, but I don't know if they're sufficient to overcome losses due to resistance in the cable.

Of greater concern is the cable capacitance. The RS-232 standard doesn't specify a max length, but it does specify a max capacitance. The general rule of thumb is that RS-232 cables should be no more than 50 feet long unless special low-capacitance cable is used. Then runs can go up to 1000 feet. Something similar probably applies to the RCU interface, only it may be much more sensitive to cable capacitance. I would try to find the lowest-capacitance multi-conductor cable you can. Twisted pair Ethernet cable might do the trick.

If you do try it, I would thoroughly test all of the RCU and amp functions, especially under transmit conditions. There's a lot of communications traffic between the two devices. In particular, I would record all of the detailed status readings that you can access from the RCU, especially the numeric forward and reflected power values and LED indicator readings while transmitting into one of your antennas with the stock RCU cable. I would also try both autotuning and manually tuning while transmitting into an antenna, and record the positions of the Tune and Load capacitors. Then add the extension cable and verify that the numbers and LED indications are the same when you scroll through them, autotune, manually tune, etc. Make sure that the RCU/2000A responds promptly to all key strokes.

If there are issues, they're likely to affect the numbers/LEDs that get displayed and the response to keystrokes. It seems likely that the CPU in the 2000A would be unaffected by communication errors with the RCU and would continue to detect faults and protect the amp. But it's possible that if the RCU detects errors on its communications interface it may try to shut down the amp. Obviously, if the amp does something funny during transmit, stop immediately.

FWIW, my 2000A is in the basement under the shack. I had to add an extension cable to the RCU cable, but the total length is probably less than 15 feet. It works fine.

Just to play the devil's advocate: I can argue about the amount of power. True that you need 6dB to have a full extra S-point but IMHO that's not what it does in real life where a few dB can make a lot of difference.

Take for example antennas where contesters and/or dx-ers have different ideas on how antennas should perform. Some look for best F/B ratio and others go for best forward gain but also there we're talking tenths of dB's and not more.

I always start from the point that a reference is a dipole at 1/2 wave above ground using 100 watts. All what you can improve is gain you can add in receive and when applying more power even more in transmit.

So going from 100 watts to 1000 watts adds 10dB but since drive power requires only 50 watts we even could talk about 12,5 dB. It's just how you look at it.

A good antenna, good coax and decent power brings you amongst the better heard stations if propagation allows. Also there a lot can be said about paths and heights and designs.

To me, I still notice a difference between going from 800 watts (very save usage of an Acom 1000) to 1500 watts (almost 3dB gain) with the Acom 2000.

I do find the 3dB to add more readability in most occasions at the opposite station. It's the same with the antenna. I went from 2 elements to 4 per band, also here the gain is noticeable better but My s-meter does not show all the time.

One thing is true for sure. If you can't make it with 1 KW you want make it either with 1,5 KW.

just my 2 cts.

It's like Olympic 100m sprints. The guy may win by only .001 second, but that's the difference between winning and losing! If you're only .1dB louder than me in the pileup, you win and I lose. In a contest, seconds matter. I will often trounce my nearby fellow competitors in contest pileups because I have the full power of my 2000A, big monobanders, and a killer QTH atop a nice hill. Every .001dB matters in my station.

If you're a casual operator, it doesn't matter. If you're a serious contester or DXer, it matters a lot!

Even One dB can sometimes be huge, especially, for example, on 160. Read this work of AB7E and take a listen to his files. Good stuff here.

I think the real value of the 1500 is that the tube it uses, although expensive will be available for some time and that it covers 6M.
Overall, at it's price point, I think it's a puzzling marketing choice for ACOM.
A 2 db power advantage could be overcome by many factors, not the least of which is operator skill and judgement.

"Overall, at it's price point, I think it's a puzzling marketing choice for ACOM".

Interesting comment.

As an Acom Dealer, the niche that the 1500 fills has been long sought-after. 1500w output 160 through 6m. Especially the 1500w on 6m part of it has been in demand. While the 1500 is being purchased and added to many stations these days, the 1000 remains in high demand too - even though it is limited to 1kW output (by spec) it represents a bargain in a 160 -> 6m amp.

The 1500 has a few new features over the 1000 which make using it very nice. The new VFD type display is clear and easy to read. Some find the 3 antenna outputs of value, some do not. I particularly like the new automatic reset from minor trip protections. Serious faults will still stop the amp cold, but normal stuff is reset just by stopping your transmission.

5489. Acom 2000a Amlifier

Yahoo group: acom-list (2010 — 2016)
Date: 2013-05-01 20:12:24 UTC
From: Ted McDonald
Topic: 5489 Message: 5489

I just bought an Acom 2000a amplifier and have it hooked up with an Icom transceiver, a Microham DigiKeyer interface, and am using N1MM for RTTY contesting. I have it set up to auto-track frequency and band changes, which it does perfectly. However, occasionally the amp receives a false signal to change frequency, which it tries to do followed immediately by the amp re-tuning to the correct frequency. I hear the stepper relays once, and then again to reset back to where it was. This may happen once an hour, or sometimes less frequently. Completely random. Has anyone else experienced this??

If your stepper has a early SDR 1000 controller Icom radios will cause the antenna to change Freq without warning ,I hope you have the keying interrupt in line . You will need to contact stepper on Monday to swap your older one with a newer rs 232 interface . In the mean time keep the antenna in manual mode . This issues rares its heads on the newer Icom Like the 7800,7600, and Pro III mostly 7700/7800 .

Also with some devices and RS-232 (not your case, as you are using C-IV) and with say Ham Radio Deluxe, by:-Going to HRD/Tools/Program Options/Comms, SELECT Only Poll Radio if HRD is Active Application--this may give another clue to you about polling conflicts.-Making sure your VFO A = B nad both track together, as the split frequency can create a frequency ambiguity that creates occasional hopping. 73, DennisN3DG

Ted,
I can not recall if the original Microham DigiKeyer had a dedicated ICOM CI-V output for amplifier control or not. If you have the radio, the amplifier and the computer all hooked together as one, such as using an ICOM CT-17 it will result in false signals exactly as you describe. The 2000A is polling the radio and butts heads with the computer.
ICOM states; Radio to computer on the CI-V buss only,nothing else. The MicroHam Digi-Keyer 2 does have an isolated CI-V output for the ICOM PW-1 amplifier to solve that problem. That is the link to use for the ACOM 2000A amplifier. Works like a champ. No polling problems.

I have it set up to auto-track frequency and band changes, which it does perfectly. However, occasionally the amp receives a false signal to change frequency, which it tries to do followed immediately by the amp re-tuning to the correct frequency. I hear the stepper relays once, and then again to reset back to where it was. This may happen once an hour, or sometimes less frequently. Completely random. Has anyone else experienced this??

5494. Acom 2000A Amplifier

Yahoo group: acom-list (2010 — 2016)

From: D G
Topic: 5489 Message: 5494

Ted, since you've put some logical thought into this, for the Non-C-IV Crowd (RS-232 folks), I suppose the use of a B&B Port Splitter 9PDMS will enable the ACOM 2000A to get the inital tracking signal, yet not poll further. I have used that model with Yaesu FTDX9000D, HRD on PC, Palstar AT AUTO and SteppIR Box. Perhaps split from the rig with one leg to ACOM 2000A RCU and the other to the PC. If you look at the datasheet, it gives a diagram on the internals/diodes for isolation. http://www.bb-elec.com/Products/Serial-Connectivity/Serial-Data-Tools-Adapters/Port-Splitters.aspx What you think ??? 73, DennisN3DG

Ted,

I can not recall if the original Microham DigiKeyer had a dedicated ICOM CI-V output for amplifier control or not. If you have the radio, the amplifier and the computer all hooked together as one, such as using an ICOM CT-17 it will result in false signals exactly as you describe. The 2000A is polling the radio and butts heads with the computer.

ICOM states; Radio to computer on the CI-V buss only,nothing else. The MicroHam Digi-Keyer 2 does have an isolated CI-V output for the ICOM PW-1 amplifier to solve that problem. That is the link to use for the ACOM 2000A amplifier. Works like a champ. No polling problems.

Topic: 5489 Message: 5496

Phil,
After reading your reply to help with the random false keying issue I have with my Acom 2000a amplifier, I see that my original message could easily be miss-understood about the "stepper" relay. I do not have the SteppIR antenna. When the Acom 2000a gets a signal to re-tune, ITS stepper relays kick in and does the tuning to the next frequency segment, or new band. Something in either the IC-7800, the MicroHam DigiKeyer interface unit, or the PC program (N1MM) is sending occasional false signals that are momentarily acted on by the amp, followed immediately by the amp resetting to where it was.
I've had several other suggestions that I am looking into now. Again, thanks for your help.

Ted,

Part of the problem is terminology. If you are referring to the auto-tune system in the Acom 2000a, using the term "stepper motors" would easily resolve the ambiguity with SteppIR relays for other readers.

Good point, Don. I realized that after sending the email. From now on, its "stepper motor" and has nothing to do with the SteppIR antennas.

A true display failure would be rare. Much more common is just having the brightness adjusted improperly. Check the manual for details about how to get the display back to full brightness.

Fred,
My Acom 2000 also has a dead display and I have not found anyone who has repaired them. The RCU works fine and if your friend,s RCU is
dead, meaning it will not turn on the amp; try reseating the cable connector inside the RCU. This solved that issue but not the display.
73's
Steve

A true display failure would be rare. Much more common is just having the
brightness adjusted improperly. Check the manual for details about how to
get the display back to full brightness.

Date: 2013-05-20 07:50:17 UTC
From: gm0kmj
Topic: 5505 Message: 5505

Hi,
Our Radio club was /P at the weekend and had problems with the club FT 950 when driving up the Acom 100 amp.
Any tips on avoidng FT 950 tripping out on TX when driving up the 1000 amp, radio seems OK till about 20 watts drive then TX trips when increasing power level. Someone suggested stray RF on the DC power lead to the FT 950, will try fitting big ferrite to the DC cable.
Any other tips ??

Ted has a good idea, Sig.

This is one of the more common errors to see on a 2000, even though this type of failure is pretty rare too - as you know.

Your amp is 10+ years old?

Give Jay a call today between 11A EST and 5PM EST and he can assist you in narrowing down what the likely problem is.

If it were mine, I'd get in touch with Array Solutions either by phone or email.

Subject: [acom-list] HV too low at startup

I arrived home tonight to find my Acom 2000A will not complete the boot up process, flatting at the end of the standby period and giving a message stating, "HV too low at startup - 0.96KV". This one is a new one on me and I am not sure what my first step should be. Anyone with experience with this or who has any ideas?

Thanks de Sig, N3RS

I hope it is not a drastic fault. You should contact Jay or Bob ar Array. They can walk you through some troubleshooting steps. If not the factory guys in Bulgaria are exceptional as well.

You will need to have the error codes ready so they can be analyzed.

5517. Startup sequence of ACOM 2000A

Yahoo group: acom-list (2010 — 2016)
Date: 2013-05-26 11:42:57 UTC
From: kangyoungtae
Topic: 5517 Message: 5517

Hi,
Can anyone let me know the startup sequence of ACOM 2000A?
Cooling fan of my ACOM 2000A does not start during startup sequence. So I wonder when cooling fan should start to run in the sequence.
I remember the sequence was as follows.
Power on at RCU -> all LEDs at RCU go to on with beep -> after about 2 second, warm-up countdown starts and all LEDs(except for POWER and STB) go to off at the same time -> after about 2 second, cooling fan starts to run. Is it right?

73,
Kang/HL5NLQ

In WPX Contest this weekend, ACOM 2000 started

tripping off from OPR to STBY and error message was ARC FAULT

Put my spare ACOM 2000 on line and no issues so I know it was no

equipment or antenna issue.

Is this likely to be the Output Vacuum Relay or the Input relay

or both ?

I had the same problem once. The cause was found was bad PL-259 connector of my antenna switcher:
diameter of central contact was a little bit less. I spent whole day to find it out by method of exclusion.

Bob

Thanks for sharing your experience but
as I mentioned - All I did was remove my
ACOM 2000 from the setup and put my spare 2000 in it's place and no issues - so the fault must be only the 2000 I took out of service - ALL other equipment and antenna switches, tuner, coax etc., remained in line !

Hopefully some other responses/experiences will come in today because I can't call ACOM distributer til Tuesday due to National Holiday here in USA

The 2000 that failed is 4 or 5 years old with only a year of serious contest time on it. My 13 year old 2000 still runs flawlessly
after 10 serious years of contesting on it !

You might try putting the "faulty" Acom back in line to see if the same
problem is still there. You want to rule out a lose cable connection.

The start-up sequence for my Acom 2000a is just like you describe below and the cooling fan DOES start about 2 seconds after pushing the red ON/OFF button on the RCU.

Ted,

Thanks for your reply.
If your cooling fan starts about 2 seconds after pushing on/off button on the RCU. Do you mean by that cooling fan starts just at same time when LEDs go to off sate? LEDs on my RCU go to off about 2 seconds after pushing the on/off button on the RCU and then warm-up countdown start from 149sec. And then all progress stops with microprocessor conflict message when countdown reaches at 138sec.

If you have a microprocessor error message you need to resolve that first.

What does it say?

Error message is just ¡°MICROPORCESSOR CONFLICT¡± with PORT LED on.
I heard that cooling fan starts when packet impulses from RCU arrive to CPU unit. And I confirmed my RCU generate packet impulses about 2 seconds after LEDs go off. So I suspect the packet impulses are delayed too much. If cooling fan starts normally about 2 seconds after LEDs go to off, I can guess at least packet impulses timing from my RCU has no problem.

You may have a problem inside the RCU unit.

Take the RCU apart (carefully) and re-install all connectors and any IC chips in sockets.

Sometimes, there is some corrosion causing problems in the RCU.

Kang,

Yes, the LEDs go out, the fan starts, and the countdown begins at 149 seconds. All this happens from about 2 to 3 seconds after pushing the Start/Stop button on the RCU. The countdown continues as the hourglass on the RCU display slowly fills the bottom half until 0 seconds is reached at which time the Amp comes on. It will be in Standby mode at this time.

hello
i like to ask if any one know i use the ACOM 1000 with one of my radio the antenna is steppir 3 ele .
i was with the antenna on 17m and move to 20m with the radio i forgot to press the 20m on the control of the steppir then start to call cq
sort i notice swr was light on the power master , and see about 250w out the aCOM SHOW 0 W NO LIGHT as well now where is the protection working in the aCOM OR THE RADIO and what sort of protection it is for the radio or the AMP ?
thank you

I've been an A1000 user for a little while. Not sure I understand the question but the A1000 does not have a different bandswitch for 17m, you use the 20m bandswitch position. Depending on issues like the length and quality of your coax, there is not that huge a difference between 17 and 20 so I think the Acom would be mistuned - maybe the attenuator may have kicked in which would be why you only see 250w out. The reflected power might not have been high enough to take the A1000 offline. (250w or so I think)

As for your rig - it would still be seeing a 50ohm load at its output so it would still be merrily putting out full output.The Acom using a broadband input rather than "tuned inputs" where the rig might have seen a high SWR and start to fold back power.

Can't be more specific without more info but hope this helps to unravel the mystery.

Regards,

Dean - 8P6SH

From: kg4lru@...
Topic: 5530 Message: 5530

I owned My 2000 A since 1999 , I recently was checking line voltage in the shack 2 weeks ago 240 was running 246 and 120 was running 126 .

Thought this was getting a little over board so I called the electric company. All grounds at the house were good and on the day they checked voltage 122.9 and 242 .

I noticed my tube gear have been running much hotter than normal and tuffer to get a stable (VFO) now I know why.

I installed a bucking transformer on 240 I was able to drop the voltage from 242 / 218 . My tube gear loves it . But Acom 2000A does not Now I get the flashing heater light . I set the main voltage on the control unit to Low setting But it did not give me any relief from the flashing heater light Is there Hard wire setting in the amp that need to be changed?

The way my shack is set up I am able to lower all 7 my 220 outlets down . I purchased the transformer for 140.00 . and it handles 45 amp draw.. I noticed my line voltage has been spot on ever since I called the electric company . They tell me 5 volts plus minus max . So they must had problem in my area , all our power is under ground until get out of the sub division .

I suspect higher line voltage has shorted some tube life here at the house . By the way you can also raise the voltage if your needing Higher voltage.

Put your amp back on your 240v line.

It can operate on up to 264v.

218v is too low.

Correct- flashing indicates you're "close" to a limit.

Don't forget that on those older 2000A units, the connectors in the filament line often go bad. A blinking "heater" LED can be an indicator that the heater is about to stop heating, regardless of your line voltage. Mine did that (also vintage 1999). I had to eliminate all three connectors in the line. FYI: I just soldered the wires in place. I've had no trouble since!

The USA standard here is 220 240 was later . the ACOM manual has several approved voltages 100.120, 200, 220, 240, 50/60 htz . I have over Ten thousand operating hours . Looks like I will need to talk with factory service people .

In a message dated 6/8/2013 1:01:55 P.M. Eastern Daylight Time, kg4lru@... writes:

I owned My 2000 A since 1999 , I recently was checking line voltage in the shack 2 weeks ago 240 was running 246 and 120 was running 126 .

Thought this was getting a little over board so I called the electric company. All grounds at the house were good and on the day they checked voltage
122.9 and 242 .

I noticed my tube gear have been running much hotter than normal and tuffer to get a stable (VFO) now I know why.

I installed a bucking transformer on 240 I was able to drop the voltage from 242 / 218 . My tube gear loves it . But Acom 2000A does not Now I get the flashing heater light . I set the main voltage on the control unit to Low setting But it did not give me any relief from the flashing heater light Is there Hard wire setting in the amp that need to be changed?

The way my shack is set up I am able to lower all 7 my 220 outlets down . I purchased the transformer for 140.00 . and it handles 45 amp draw.. I noticed my line voltage has been spot on ever since I called the electric company . They tell me 5 volts plus minus max . So they must had problem in my area , all our power is under ground until get out of the sub division .

I suspect higher line voltage has shorted some tube life here at the house . By the way you can also raise the voltage if your needing Higher voltage.

Hello Fred

If you find out let me know,I just sorted one problem out involving the screen voltage on my Acom.I then went away on holiday for 2 weeks came back, turned it on, and theres no display.

Other than that it works fine, and still produces power.

I used to love my Acom 1000 but now Im starting to hate the damn thing !

It's most likely that the backlight adjustment has become dimmed by mistake.

Check the manual for instructions on how to adjust the display backlight.

I've only seen one bad display in over 10 years of working with the 1000.

Thanks for the info but Ive tried that.

Strangely Acom 1000 does not appear in the display when the amp is off,and Im sure it used to.

When I get some time I will investigate and report back !

5539. Bias Too Low

Yahoo group: acom-list (2010 — 2016)
Date: 2013-06-16 15:25:41 UTC
From: Hank Garretson
Topic: 5539 Message: 5539

Ouch.

Turning on ACOM 2000A this morning:

BIAS TOO LOW AT POWER ON: -000V

Manual recommendations are OFF5* and CCC*.

I tried (several times) after five minutes. No joy.

I disconnected cable from transceiver to ACOM Key-in. No joy.

Unit operated normally yesterday during All-Asian and Ukrainian RTTY.

Late evening, I attempted to get on for Stew Perry 160. Using ACOM above 150 watts resulted in ARC fault. Gave up on 160. Returned to Ukrainian RTTY and made a few more contacts before shutting down. ACOM operation on other bands was normal after the ARC fault on 160. ACOM shutdown to go to bed was normal.

Ideas? Suggestions?

73,

Hank, W6SX

Mammoth Lakes, California

Elevation 8083 feet in John Muir's Range of Light

In April the identical problem happened to my 2000A. Array Solutions replaced all four zener diodes in the bias supply that makes the -124 VDC and replaced both tubes. There was probably a gird short (when the tubes failed) that took out the zeners. Brace yourself, repairs $250.00, pair of tubes $600.00, plus shipping both ways.

Check the power supply board(s). I recall an electrolytic being smoked on mine (C2, I think, but I can't check right now). If yours is smoked (it's visibly obvious), let me know. I bought some extras and I'll gladly give you one.

From: Hank Garretson
Topic: 5543 Message: 5543

Thank you everyone for your suggestions, and thank you Glenn for the offer of capacitors. Jay at Array Solutions has been very helpful.

I have the 2000A apart with the low-voltage board sitting on my test bench. Diodes check OK. Capacitors look OK, but on Jay's suggestion, I have ordered replacements for all electrolytes on the board from Mouser.

Stay tuned, and thanks everyone for your help.

ACOM Exuberantly,

Hank, W6SX

Mammoth Lakes, California

Hi Hank!

"Elevation 8083 feet in John Muir's Range of Light"

Maybe your elevation is the culprit! Bias voltage is inversely proportional to elevation! :-)

GL OM ES VY 73 de Glenn K3PP
The capacitor offer remains on the table if you need it, but it appears you've covered that issue!

Hank, I also ordered a few extra C2's, and would be happy to send you one If that's what you need. My low bias problems have always turned out to be a grid short in one of the tubes.
They are tricky, I had one that only did it hot. I had to pull it out hot (oven gloves) and on an ohmmeter you could see about 20K ohms from the control grid to ground. You could watch it cool off and the resistance would go back up to infinity. Easiest to test by substitution.

73,
Hal

Geeze Louise, guys! Last year I rewarded my 50th anniversary as a ham with a new 2000A, but I was quickly scared into buying a spare pair of tubes. Now it sounds like I should begin stocking up on caps. I guess I should have bought two: one to use and one for spares. :(Too bad I could barely afford the first one.

Dick

Fear not, Dick! The newer units are flawless. The first wave (vintage 1999-2001) had problems. Mine was one of the first in the US. Cap C2 blew as did my Molex connectors for the filament line, but tubes are still original!

From: Jay Terleski
Topic: 5548 Message: 5548

Capacitors, in older units are starting to dry out, and they did have a batch of caps that were less than desirable.

But, I suggested to hank that since he will take the LV board out that he may as well replace all of them, for what little money they cost and these days you can get higher rated electrolytics that are as small or smaller then the ones sold 5-10 years ago. For instance the 25V caps can easily be 50V caps, etc.

Regards to the group
Jay, WX0B

Electrolytic capacitors are probably the least reliable component in electronics today. The capacitors have changed greatly in the past 50 years and with some minor batch exceptions the change has been for the good. Temperature ratings have risen, component densities have risen, ripple current ratings have risen and an enormous amount of data is available. The biggest thing you can do to improve reliability is to lower the temperature (every 10 deg C approx. halves the life) but since that isn't easy to do using components rated at 105 deg. C or even 125 deg. C and using parts rated at at least 2X or 3X the needed voltage will probably make the capacitors life longer than yours. The automobile industry has driven the availability of the 125 deg C parts and I would always stick with a good capacitor brand such as Nichicon, Kemet, AVX, Panasonic etc. and stay away from swapfests, NOS junk, and eBay unless you are very careful.

There are a couple of big unknowns with capacitors. The first is temperature ratings are internal to the part and that ripple current raises the capacitor temperature above the ambient temperature. This is much more important for filter capacitors in power supplies. The other is mounting stress especially for surface mount parts. Soldering the capacitor to an unheated PCB causes a continual stress which can cause failures.

All of this has been known for many years. When I was designing products is was routine to de-rate electrolytic capacitors 2X for voltage and tantalum capacitors 3X and this was in the 1970s and 80s.

Before you try to remove all the capacitors from a PCB ask yourself if you are capable of doing this without ruining the PCB. Surface mount parts are easy to remove but thru hole parts really need a good solder sucking machine like a Hakko 808 which might seem expensive at about $180-$200 but with a tool such as this parts can be removed all day with no PCB damage. Sometimes the PCB holes are a little too small for the component leads and you ruin the PCB trying to use the bulb or spring suckers or desoldering wick. Just my $.02. Practice on some junk PCBs before is a good idea.

Topic: 5548 Message: 5550

Hi Jay, That does look like quite a useful desolder station. I see it got great reviews except one person mentioned the stiff cord. I will most likely get one. I have never done surface
mount work, eyes are fair and I do have mag glasses but wonder if you have a suggestion on surface mount station or equipment.

Regarding the Acom bias issue, I had mentioned I too had it and drove my Acom to them when they were in MA. I watched them fix it which the first thing they did was remove that cap. If I am correct about it, it looked like quite a job getting to it. The problem ended up to be a def tube. They replace both tubes and never charged me for any of the work. It was a used Acom I bought from them a few years prior. Great people and great amp which I have had since 2001.

Gl with the repair.

Steve

Acom 1000 Amplifier Serial Number 020175

I am selling my Acom 1000 amp. It has recently been repaired by Array Solutions and restored to original factor specs. Both the Screen Grid and Bias circuitry were repaired by Arry Solutions. In addition, I replaced the external (Output) vacuum relay with one recommended by Acom.

I am the original owner. The amp is in excellent condition and I am a non-smoker. I do not have the original box. I will ship the original manual separately from my home QTH to the buyer.

The amp will be shipped from Array Solutions, in Texas and will include their repair warrantee.

I am asking $2,600 + shipping from Texas.

The amp is also listed on QTH.com

If you are interested in purchasing please email me off the reflector at KD3TB@...

From: Robert
Topic: 5552 Message: 5552

This past weekend there was an opening on 6 meters so I decided to use my new ACOM 1000 for the first time on 6. With the 6 dB attenuator switched in I did the initial tuning. Then I switched the attenuator off. As soon as I keyed the amplifier I got an "ARC Protect" error message. So I reduce the drive power and tried again and got the error message again. My 6 meter antenna has an SWR of between 1.4:1 and 1.8:1. Any ideas as to what is wrong?

The key words "for the first time"

Clearly you have a fault in your coax, connectors or antenna that can't handle the power without arcing.

Is there a power level that doesn't arc?

I have run this antenna system at 100 watts for two years without any problems. I will try running reduced power into my Heathkit Cantenna.

5555. Bias Too Low--Fixed

Yahoo group: acom-list (2010 — 2016)
Date: 2013-07-07 14:54:27 UTC
From: Hank Garretson
Topic: 5555 Message: 5555

My ACOM 2000A is fixed and back on the air.

The problem was a shorted tube.

I purchased the amplifier new in August 2009. The tubes had 83,624 contest QSOs on them. Two new tubes cost $628 from Array Solutions. That works out to 0.75 cents per QSO. A bargain in my book.

Great support and lots of help from Jay, Sharon, and Bob at Array Solutions. Thank you.

73,

Hank, W6SX

Frank

This is relatively simple exercise. There is also a file somewhere (maybe in the files section) which gives step by step instructions.

This link gives some info:

http://www.m0oxo.com/radio-projects/acom-1000-mod.html

This fan is a 24V and can be obtained from many suppliers - I used a PABST but I believe there are several other models available.

Actually found the file on my computer - I thought I'd lost it. I have simply cupy and pasted:

ACOM1000 External Fan Installation
---

1. Remove the top cover. Unscrew the mounting bolts of the power transformer. Copy the position of the mains voltage selector before disconnectign transformer wires. Disconnect all connectors of the transformer and take it out of the amplifier.

2. Remove the air filter from the chassis inlet opening. If you have a metal finger guard supplied with the fan, please put it at the internal side of the amplifier. This would reduce eventual RF radiation through the opening. Install the external aux fan on the external side of the opening. Please note the air flow direction (usually marked by an arrow on the fan body): the fan must suck air from outside and it must pump it into the amplifier volume.

You'll need longer screws for this purpose. Meanwhile, this is the reason that we have not used self-clinching nuts for these screws: the user would be obligated to find metric screws.

3. You can use a connector with insertable contacts of the type CST-100 from AMP. Crimp or solder the contacts to the fan original wires and then thread them through the holes (about 5mm diameter) that are foreseen in the MAINS PCB and the aluminium chassis below the PCB. At last, insert and clinch the contacts into their plastic body.

4. Install the original air filter on the back side of the fan using another four screws. It must be accessible for periodical cleaning.

Hope that helps

Dean

From: barrie_spink
Topic: 5560 Message: 5560

I have just replaced the valves in an Acom 1011 amplifier, I am seeking a Service Manual, operational manual and if all else fails an Electronic schematic. Can any body help me..
I would also be interested to know if any of the other moels are similar to the 1011 model
Thanking You

Barrie P Spink GM0KZX

Barrie

I have never actually seen nor do I have the documents you're asking about. I do believe the 1011 is very similar to the 1010 BUT because one uses a single tetrode and the other 2 tetrodes there are probably enough variations in the circuitry in the areas you would need which would make the 1010 information of only limited use to you.

I am not sure where you purchased your Acom BUT you should be able to email the dealer and obtain an electronic copy of all the information you need. Failing that an email to Val, LZ1VB at acom@... should also get you that information. He's a great guy and helped me a short while ago in resolving a tricky issue with the A1000.

Cheers,

Dean - 8P6SH

5563. 2012 ACOM 2000A with old type RCU for sale

Yahoo group: acom-list (2010 — 2016)
Date: 2013-07-29 19:47:13 UTC
From: Jay Terleski
Topic: 5563 Message: 5563

Hello List.
Here at Array Solutions we have one 2012 ACOM 2000A with the older RCU left.
It was used at Dayton for a demo in 2012 before the new RCU was out. So it
has very low tube time on it.

We offer it with brand new Warranty (2 years, 1 year on the tubes).
New 2000As are now $7950.00
This one is $6850 which includes free shipping to lower 48 states, and
accommodation credit of $75
outside the lower 48.

This amp is in new condition.

Give us a call if interested.

Acom 1000 Amplifier Serial Number 020175

Contest Season is starting soon and it's time to think about updating your station.

I am selling my Acom 1000 amp. It has recently been repaired by Array Solutions and restored to original factor specs.

I am the original owner. The amp is in excellent condition and I am a non-smoker.

The amp will be shipped from Array Solutions, in Texas. I will ship the original manual separately from my home QTH to the buyer.

I am asking $2,600 + shipping from Texas.

If you are interested in purchasing please email me off the reflector at KD3TB@...

Irwin, KD3TB

5565. Acom 1000 bias too low to achieve 220ma plate current

Yahoo group: acom-list (2010 — 2016)
Date: 2013-08-16 16:43:50 UTC
From: g3xrj
Topic: 5565 Message: 5565

Trying to set standing current with RP2 and unable to get below 350ma with 3w drive.
Working on Acom Schematic P16 of 25 which is Mains Sht 2 of 5.
Bias volts on JP4 pin 5 -38v.
Left side of R16 -130v key up -86v key down.
I feel this left side of R16 should maintain -130v key up and down ?
I cant find any problem with rectifier circuit D7-D9 D10 etc.
Changed C15 without effect.
Lifting left side of R16 then top of R14 maintains -130v key up/down.
Re-connecting R16 the 50v developed across it indicate a current of 2ma through it.
Questions
1) Is the 2ma sufficient to trip Q1 which I assume to be crowbar protection.
2) what is purpose of 7.5v Zener D11 which despite replacing it only shows 3v across it.
3) What is purpose of Q6
4) Q7 appears to be instrumental in Bias controlled by RP2 and metering circuit U2B etc.

Removing the 4cx800 and JP4 makes no difference to voltage readings.

Can anyone improve my understanding please

John G3XRJ

5569. Acom 2000s controller failure

Yahoo group: acom-list (2010 — 2016)
Date: 2013-08-26 00:02:19 UTC
From: AB2E Darrell
Topic: 5569 Message: 5569

Hi,
Wonder if anyone with the 2000S antenna switch and controller have had this problem....if so, how did you resolve it?

It had been working fine with the Acom 2000A.

Went to turn on the 2000s tonight which I do prior to turning on the amp, the LEDs were out, and there was a buzz/hum/vibration coming from the box.

I tried unplugging the control cable to the antenna switch, and got the same result.

Thanks and 73,
Darrell AB2E

Yes. No problem. The amp just needs a ground to key. I use it on an Acom 1000 with an FT-2000, 3000, and 5000MP. Forget that linear plug. It is more for band data to a VL-1000

The lighting could be LED - not sure, but it sure looks great.

No power to the tubes with just the main switch on. Only low voltage to the RCU and other controller related components at that point.

Not quite correct if we are talking the 2000A. With the power switch ON
and the RCU OFF, the bias supply is alive. There is something like
-125V on the screen grids. Otherwise the tubes are un-powered however..

The manual states that I your intentions are not to use the amplifier for several hours to switch off the main power switch. I let it on only when I know I'll be using the amp later on, otherwise if I'm not using it anymore that same day, I switch it off. When on, the displays shows your call sign if programmed.  Fred, 'ACOM 1000' shows on the LCD when power rocker switch at rear is ON but the amp is OFF on the pushbutton. Without power only the tiny dashes and numbers for the power graph along the top are visible all the time (printed?)   Why don't you ring Ron at Vine Antennas - he's really helpful and can certainly fix you up with parts if nothing else.   Steve M1BJR Somerset. --- In acom-list@yahoogroups.com, <g4rra@...> wrote: Thanks for the info but Ive tried that.

Strangely Acom 1000 does not appear in the display when the amp is off,and Im sure it used to.

It's most likely that the backlight adjustment has become dimmed by mistake.

Check the manual for instructions on how to adjust the display backlight.

I've only seen one bad display in over 10 years of working with the 1000.

Confusing emails with all sorts of rubbish codes embedded.

However, to whoever, with the Acom 1000 fully off, that is, switched off at the rear, there isn't any banner display. With the rear switch on, red light on the front, the banner is displayed.

Brian, send me an email and I will forward a copy of the error code spreadsheet, it's only 55KB.

Thanks Sulaiman

Its been a while since my original posting and it turns out this is exactly what I did..and the display reappeared.

So far its not done it again,so if the display disappears but the backlight is still on just try switching it off on the rear switch and then switching it back on again..it worked for me.

After I had done it I wondered why I had not thought of it before,but I guess most of us just switch the main on/off switch on rather than use the rear switch.

Acom 2000A for sale, as new condition.

Purchased 7 March 2012 from Vine Antennas.
Only 105 hours running time, mark 1 RCU, manual, original transport boxes.

GBP3000, carriage extra.

5584. Acom1000 PN07 fault code

Yahoo group: acom-list (2010 — 2016)
Date: 2013-09-25 17:46:36 UTC
From: Larry Benko
Topic: 5584 Message: 5584

Hi Icom folks,

Acom 1000 was on and in standby. Fault occurred and amp tripped off.
Now trying to turn on amp gives the following fault code:

1APN07 000000 000000 1B0095 0400DD DF6E5E

The 7 in the first group (1APN0*7*) indicates a high voltage failure and the 00 in the 4th group (1B*00*95) indicates the voltage = 0. The 95 in the 4th group(1B00*95*) indicates a temperature of 25 deg. C (2*hex2dec(95)-273) which is about right. The amp is stone cold which indicates to me that the A/D reference voltage is OK. Have I interpreted the fault codes correctly?

73,
Larry, W0QE

Larry,
Yes you have a HV fault. Check the HV diodes, and the 3M resistor and HV measurement circuit first on the HV board.

Unplug HV wire, and turn on amp with cover on of course. See if it warms up. If so you have a tank issues bypass caps, or even an Anode short on the tube.

5586. acom 1000 PN27 on start-up

Yahoo group: acom-list (2010 — 2016)
Date: 2013-09-28 15:08:33 UTC
From: Terry G4AMT
Topic: 5586 Message: 5586

Hello
After months of faultless operation, my Acom 1000 failed on start-up
this morning with the following string:-
1APN27 000000 000000 1BCE94 0760DC D76FDA

I am - hopefully correctly - interpreting this as High HV - it looks
like `hvm, V 3296`.
R13 - the 3M resistor pack seems to check out ok; so I am suspecting the
power diodes or similar in that area.
Any advice would be much appreciated.
Thank you.
Terry

Hi Terry

I hope your luck is better than mine. I would advise you contact the factory and get one of the technicians to walk you through the trouble-shooting procedure. Basically I had a similar problem and its essentially a HV fault. I had many of the same suspicions you had but it turned out to be a short between the HV and the LV windings on the secondary of the transformer. The test for that is to check the resistance between thevarious windings mine were something like this:

The inter-coil resistance is as follows:

120V winding resistance: 42 ohms
305V winding resistance: 16 ohms
2050V winding resistance: 100 ohms

2050V winding to 120V winding: completely open no reading at most sensitive
2050V winding to 305V winding: 300 k-ohms

120V winding to 305V winding: completely open no reading at most sensitive

Should I suspect that there is a problem between the 305V winding and the HV winding??

AND the answer was YES I had some leakage between the 2050V and the 305V windings.

I would check this first and if you are lucky you will not have a short here and then I can tell you what other tests they asked me to do and I will give you email address for Stan at ACOM <acom@mail.orbitel.bg>. He will talk you through it. AND actually I
might have had a PN07 error not a PN27 BUT I have had 2 Acom 1000 and had major problems with both. I am now changing the transformer on the second after selling the first. I will probably still purchase an Acom 1500 as
this problem is one of customised transformers which was not as big a deal with triodes which only required a HV supply. These amps are a bit more complicated and work well until they develop faults which are often expensive
and difficult for the user to diagnose.

Regards

Dean

Dean,

Just 2 days ago I had a PN07 fault (1APN07 000000 000000 1B0095 0400DD DF6E5E) which turned out to be a short in the transformer between the HV and AC winding (1-2-3-4). It took out a diode in the HV bridge and both R1A & R1B in the plate current detect on the HV board. Analyzing the circuit with such a short easily shows how damage to both parts occurs. Removing the transformer from the amp still shows the same short. I now have a inquiry out as to the price of a new transformer.

While inspecting the main PCB I also found a bulging and ready to fail electrolytic cap (C5 3300uF @ 25V) which I replaced. BTW my Acom 1000 was bought in 2001 and has been a good performer until now.

Hi,

Also had the PN07 trips last year and as I have more than one Acom 1000A bought a spare transformer which was in excess of £400 shipped to the UK. The problem turned out to be a zener in the EHT sampling chain that was short and telling the control circuit that there was no EHT. Fortunately that repair was very inexpensive...other than buying the spare transformer :)

Sorry to hear that. My transformer quote was 362 Euros and then shipping another 100 Euros. I believe mine was purchased at around the same originally and I bought from the owner in 2005.

Regards

Dean

5591. ACOM 2000A Problem

Yahoo group: acom-list (2010 — 2016)
Date: 2013-09-29 13:23:22 UTC
From: Richard Zalewski
Topic: 5591 Message: 5591

While operating in the RTTY test my amp suddenly shut off. I discovered both line fuses had blown. After replacing them the amp powers on but after the warmup it shuts off with the error message LOW HV ON STARTUP.88KV.

I saw in the achieves that others had the problem but I did not see any solution.

Terry,

If the amplifier is set to the right mains voltage, 3296V could be result of a metering error only. The usual suspect is the 3M resistor. Sometimes it's quite a tricky and checks out OK with an ohmmeter but fails when the HV is applied. If your resistor is of red/brown colour, it's capable of such a dirty trick.

Generally speaking about the error codes showing HV malfunction, one should have in mind that an error showing a missing HV isn't bound to a HV failure. A low voltage supply fault wouldn't allow the HV transformer turning on at all. Same with the soft start resistors, power on relays and fuses. The relay clicks at power on or their missing are a good indication where to look.

From: Terry G4AMT
Topic: 5598 Message: 5598

Thank you to all who responded on and off list.
The fault was indeed R13, the 3Mohm package resistor - this checked out fine with an ohm-meter, but was causing the start-up failure.
A near identical replacement is available in the UK from RS Components 296-0689

Hi

Since no-one has responded there are quite a few messages and it might be useful to search the archive.

This I think fans a UV fault. The last problem like this was the 3 mega ohm resistor used in the metering circuit. You may wish to start by checking out that resistor.

A search of the archives would be quite useful.

From: Mark Robinson
Topic: 5605 Message: 5605

I have an Acom 1000 which seems to be working perfectly but the Screen Current reads 0 mA at all times.

What should it read and where should I look for the problem.

thanks and 73 Mark N1UK

5606. 1APR27

HI Val!

This morning after warmup I pushed OPER button and got an ARC.
Turned off then on again and all is working fine all day.
I now have errorcode 1APN07 000000 010000
Not often but when I want to run only 100 watts for some
local qso's without turning off the linear I turn OPER off.
I can't get any power bypass the linear. Like no antenna.
Any idea Val?

Group,

I just got a fault on the RCU, "Microprocessor Conflict." Never saw this one before. Amp was working a couple of days ago.

Any ideas for a fix?

73 - Dave N3RD

5608. 2000A Fault: Microprocessor Conflict - Resolved

Yahoo group: acom-list (2010 — 2016)
Date: 2013-10-08 01:02:32 UTC
From: Dave Hawes
Topic: 5607 Message: 5608

I subsequently discovered that the plug on the cable from the RCU had come partially loose from its jack on the rear of the 2000A. Not loose enough to prevent the startup from being initiated, though. I'm blaming this on the new kitten...my story and I'm sticking to it.

From: Richard Zalewski
Topic: 5609 Message: 5609

I have an Acom 2000A with the factory extra cooling fan. I have always run extra fans on the tube exhausts of my amps but have not done so with the 2000. Anyone see a problem of running a couple of muffins on top of the tube exhausts?

From: Brian Alsop
Topic: 5609 Message: 5610

This is my understanding:

The airflow of the muffin fans must be at least as much as the primary cooling fan. Otherwise, it results in a constriction which actually can result in higher tube temps.

I don't think it will hurt, but it's probably not necessary. I run mine in RTTY contests at full power and have no problems with the heat getting anywhere near the max permitted. Ironically, the most heat dissipation in the 2000A's is on SSB since the idling current is so high. Even 1 Watt input will trigger the bias to become less negative and result in about 1,000 Watts DC on the plates. This weekend in the California QSO party, I saw the temp go up to about 60 C on long SSB runs, but that's well below the rated max.

Hi

Extra fan is really needed in my amp.

If I run RTTY pileups and call CQ long time, temp goes up to 90 C without extra fan.

With extra fan, temps go up to 70 - 80 C .

I do that way using an extra fan behind the tube´s chimeneys sucking the hot air out and another one behind the extra cooling fan blowing fresh air into it. My amp is inside a wood cabinet (see my pictures on qrs.com) and the top shelf was a bit warm till I installed those fans. So far so good and hardly ever see 50 degrees (Celsius) on my RCU.

5616. Heater Current Too High and 12v Too High

Yahoo group: acom-list (2010 — 2016)
Date: 2013-10-12 17:45:16 UTC
From: Jim Idelson
Topic: 5616 Message: 5616

High everyone,

I have two Acom 2000A amps that have not been used for a couple of years. Just powered both of them up.

* Amp #1
o Initial startup cycle failed with Heater Current Too High
o Second and later startup cycles are failing with 12V Too High
* Amp #2
o Always fails fairly early in the startup cycle with Heater Current Too High

I saw the recommendation that we check line voltage - I will check that now. I am plugging into the same 240vac outlet as always.

Any other thoughts?

5617. Acom 100 fault

Yahoo group: acom-list (2010 — 2016)
Date: 2013-10-13 20:59:38 UTC
From: <gordon.paterson@...>
Topic: 5617 Message: 5617

Wondering if anyone can advise please.

My Acom has developed an intermittent fault

1A TR6B 000000 000100 1bb198 7720DC D77FC1 2A SB2B 000000 000000 2BB198 0720DC D77FF7

3A TR6B 000000 070100 1bb198 7720DC D77FC6

The fault codes listed which are all generated usually while powered on and offline and when I move the Band switch. It doesn't happen every time and the amp works correctly once it is on the appropriate band. It doesn't usually happen if I move the band switch while it is still online but I have a habit of putting it offline before switching bands and resetting tune and load.

Reading from the manual I see this info regarding the two different fault codes

TR6 - antenna relay tests made during Rx (Operate mode)
B - output relay closed (ORC, logic)

SB2 - tests made during Stand-By, after the warm-up period;
B - output relay closed (ORC, logic)

Both of the faults point to Output relay closed (ORC logic) according to the manual. So any advice on what may be required please?

To be clear, the amplifier then works flawlessly for hours and seems to have no issue as long as I don't have to change band. Worse case scenario currently is that I need to hit the on/off after a reset and it will start up again in 10 seconds if I do it immediately.

Hi Barry,

When I installed mine, I just went to my location´s electronic shop and I bought a good one, quiet, with ball bearings I guess, 24V, and it is working great, so far.
I need to say that it only turns on when temperature is over 80 or 85 degrees celsious. Only happens during heavy contest, digitals, etc.

So, don´t spend too much time thinking about it, just buy a good fan, install it and enjoy...

5628. Acom 2000a auto band change

Yahoo group: acom-list (2010 — 2016)
Date: 2013-10-26 07:36:43 UTC
From: ON4VP
Topic: 5628 Message: 5628

Hello group,

I was wondering if some software is on the market to make the Acom 2000a follow my radio when qsy to other band.
I know it does it quick when sensing RF but the serial connection is also there.

I've been using Acom Director, a nice graphical interface but it lacks a CAT connection to the radio.

Any suggestions.
I'm using logger32 and it supports Alpha 87a but no Acom :-(

This function is provided by the new design RCU.

You can replace / upgrade the original RCU on any 2000A to make it follow your radio.

TRX-Manager has a module specifically supporting Acom automatic band changing and antenna switching when using the Acom antenna switch.

Hi Phil,

I think Acom has a software/driver for a computer to "listen" the band switching from the radio and manage the Acom amplifier and remote Acom antenna switch;

http://www.acom-bg.com/antsw2000S.html

The idea is to connect radio and Acom to computer, using his RS232 ports, then a simple driver program is listening the radio then switching the Acom, even in RX. This applies to the Acom 2000S remote antenna switch as well.

TRX-Manager has an add on program, TRX-Acom, that does this. But you must use TRX-Manager to control the rig for it to work.

I have no problem with Logger 32 following band changes. My Acom 2000a is about a year old, connected to a IC 7800. In band and band changes of frequency are instantly reflected in Logger 32. Sometimes the 7800 will send a noise spike (or something) that causes the 2000a to change frequency, but the 2000a senses the incorrect frequency and changes back to where it was immediately. I know the 7800 is causing this because when I disconnect the CIV cable at the rear of the 7800, the false frequency changes stop.

I guess having the amp track on QSY might be nice, but the 1 sec auto band change in the 2000A is jus fine for me. My logging program follows my 7600 just fine and the 2000A tags along ONE SECOND after I transmit.

Really not a BIG DEAL!

From: daedalusnj
Topic: 5636 Message: 5636

I'm looking at possibly buying an ACOM 1500 rated 1.5KW SSB and 1.2KW RTTY (and other). Does "other" include AM? Has anyone one here actually used a 1000 or 1500 on AM? If so, what has been your experience?

I'm running an early 1011 now (basically a 1010 in 1011 skins) and getting the urge to upgrade. The 1011 is good for a solid 600W out on SSB and I am happy with it but considering going full bore!

Second question: I can call Array Solutions but curious if anyone knows if they accept trade-ins.

Thanks & 73

Yes - since AM is a continuous carrier mode, you should limit your peak output to about 1200w for long transmissions.

Also, if you're running a classic AM transmitter, your carrier power (no modulation) will be only about 25% (300w) of your peak power (1200w) at 100% modulation.

5640. "External" fan install question (2000A)

Yahoo group: acom-list (2010 — 2016)
Date: 2013-10-31 20:33:39 UTC
From: Barry N1EU
Topic: 5640 Message: 5640

I'm hoping somebody could give some guidance on the 24VDC connection when adding the "external" fan to the rear panel of the 2000A. There's a small pcb protruding from the shelf under where the fan goes. There are two drilled solder pads labelled EXT FAN DC + and -

I assume this is where to wire the fan. But I measure zero ohms resistance on both pads to chassis ground. Is this the correct place to wire the fan? Perhaps when the amp goes up in temperature a relay kicks in and connects the pads to dc?

Thanks & 73,
Barry N1EU

hi

Yes I am using a Mac, my software is Dogpark's MacLoggerDX . That talks to a Microham microkeyerII which is connected to my radio. The microkeyer has a extra serial port(ci-v) that will talk to the Acom's (w/new RCU) s port.

I made the acom serial cable as directed in the manual.

The new amp works really fantastic following the radio as I tune around the bands and is therefore always ready to go even before I tx.

The amp also can sense rf really quick so I wouldn't say you have to use that method, just something that suits my particular style and I can say both works really fantastic! wouldn't trade it for anything

Hi Barry, I would be interested in your findings when you have the external fan fitted on the 2000A. I have a client asking me if it is a worthwhile addition and to be honest, I have been running Acom 1000 and 2000A units for years quite successfully with no external fan but not to say that the fan is not a worthwhile project. I ragchew with my amp a fair bit and even with my excessive talking on air, the amp just cranks along without fail. That being said, we are the Dealer for acom here in Australia and have been for many years so we are biased haha..As for the connection points, I agree that you seem to have the fan connected correctly to the right terminals so it may be a question of temperature sensing that may need to be investigated. I love the Acom amps, even if we were not professionally linked to Bulgaria, I would run these amps without question. I love the support we receive from Bulgaria, no question is considered stupid and they have some pretty bright people on board thats for sure. If you get into trouble, email Stan at Acom and I am sure he will send you back some quick thoughts as well. Jay and Bob at Array Solutions are also incredibly helpful so just another local option for you as well.
cheers
Brenton

The issue for me is that this will be almost impossible to troubleshoot, because to get access to the fan electrical connections you have to pull the xfmr (and there goes your power). If someone can tell me of a constant source of 24VDC, then I'll wire it to that and be done with it. Otherwise, I'm going to install a 120VAC fan and just plug it in externally.

I already pulled the cover under the tube deck and double checked that the fan circuit jumper is in the 24V position and not the 12V position.

Barry,

The fan only comes on when the amp is too hot.

I installed an external fan on mine, and I have only had it run once.

It was in the summer, without air conditioning on, and it was in the 90's
in the shack - and I was running RTTY calling long CQ's.

When it came on, it surprised the heck out of me.

Why are you installing this fan? Is your amplifier overheating?

hi

My 12v extra fan installed by myself, a computer fan, blow all the time, slow but blow never stop.
I heard only one time blowing fans of this amp very strong around 90 deg if i remember.

As i never use this amp to full power and not long time and long QSO or numerics modes, fans never blow strong.
